Roots of polynomials

References: Chapters 5.1, 9.5 of *Numerical Recipes Third Edition* by W.H. Press et al.

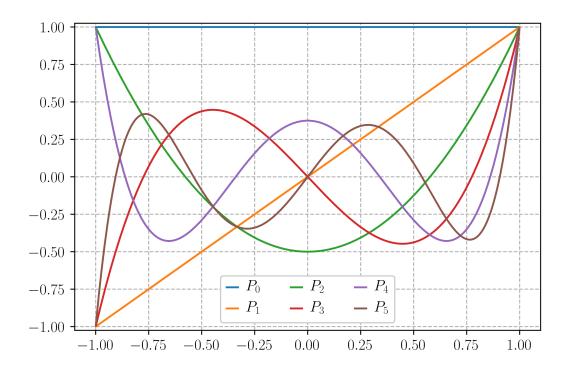

Roots of polynomials

So far we've dealt with polynomials with one real root, such as

$$x^3 - x - 1 = 0$$

Other polynomials (e.g. **Legendre polynomials**) have multiple real roots, and we need to calculate them all

Preliminaries: evaluating polynomials efficiently

A polynomial can typically be written as

$$P(x) = \sum_{j=0}^{n} a_j x^j$$

or, equivalently, as

```
P(x) = a_0 + x(a_1 + x(...))
```

which allows one to evaluate both the polynomial and its derivative efficiently

```
def Poly(x,a):
    ret = a[len(a) - 1]
    for j in range(len(a) - 2, -1, -1):
        ret = ret * x + a[j]
    return ret
```

```
# Evaluate the derivative of a polynomial
# with coefficients a at a point x
def dPoly(x,a):
    p = a[len(a) - 1]
    dp = 0.
    for j in range(len(a) - 2, -1, -1):
        dp = dp * x + p
        p = p * x + a[j]
    return dp
```

Preliminaries: multiplying and dividing a polynomial

Multiplication:

Multiply
$$P(x) = \sum_{j=0}^{n} a_j x^j$$
 by $(x - c)$ to get $\tilde{P}(x) = (x - c) P(x) = \sum_{j=0}^{n+1} \tilde{a}_j x^j$.

Easy to see that

$$ilde{a}_0=-ca_0, \qquad ext{and} \qquad ilde{a}_j=a_{j-1}-c\;a_j, \qquad j=1,\dots$$
 , $n+1$

Division:

Inverting these relations defines the division of $\tilde{P}(x)$ by (x-c)

$$a_j = \tilde{a}_{j+1} + c \, a_{j+1}, \quad j = 0, \dots, n$$

Note that the division only makes sense when x=c is a root of $\tilde{P}(x)$

Multiply polynomial by (x - c)
def PolyMult(a,c):
 n = len(a)
 ret = a[:]
 ret.append(ret[-1])
 for j in range(n-1,0,-1):
 ret[j] = ret[j-1] - c * ret[j]
 ret[0] = -c * ret[0]
 return ret

```
# Divide the polynomial by (x - c),
# assuming x = c is one of the roots
def PolyDiv(a,c):
    n = len(a) - 1
    ret = a[:]
    ret[-1] = 0.
    for j in range(n-1,-1,-1):
        ret[j] = a[j+1] + c * ret[j+1]
    ret.pop()
    return ret
```

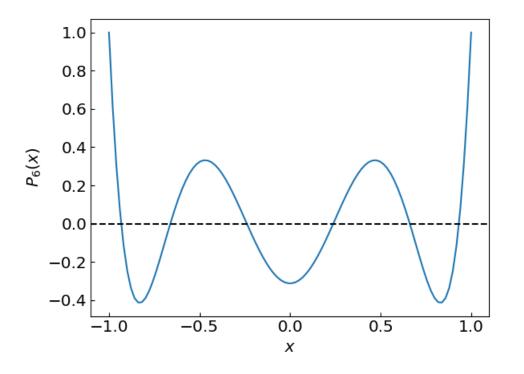

Roots of Legendre polynomials $P_n(x)$ play an important role e.g. for numerical integration using quadratures

Each $P_n(x)$ has *n* real roots in the interval x = -1...1

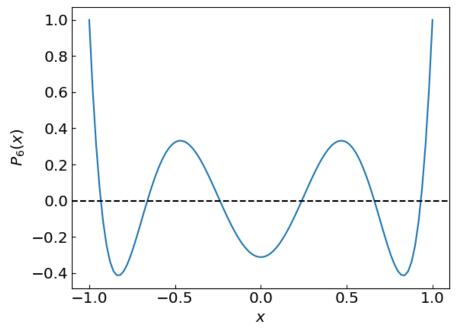

Consider

$$P_6(x) = \frac{1}{16} \left(231x^6 - 315x^4 + 105x^2 - 5 \right)$$

How to evaluate its six roots accurately?

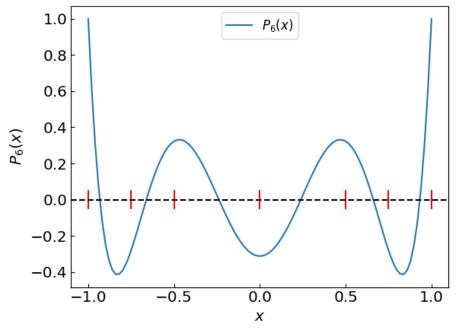

Strategy 1: Bracket each root from visual analysis and use the bisection method for refinement

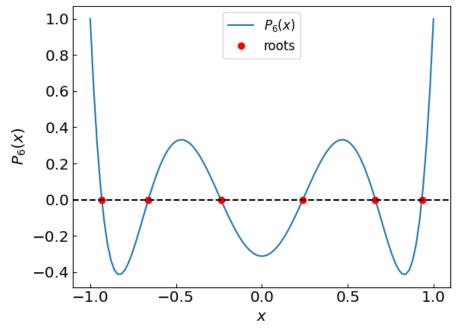

Strategy 1: Bracket each root from visual analysis and use the bisection method for refinement

```
xroots = []
# Root 1
xleft = -1.
xright = -0.75
xroots.append(bisection method(fP6,xleft,xright))
print("Root 1 between", xleft, "and", xright, "is x =", xroots[-1])
x = -0.75
xright = -0.5
xroots.append(bisection method(fP6,xleft,xright))
print("Root 2 between", xleft, "and", xright, "is x =", xroots[-1])
xleft = -0.5
xright = 0.
xroots.append(bisection method(fP6,xleft,xright))
print("Root 3 between", xleft, "and", xright, "is x =", xroots[-1])
xleft = 0.
xright = 0.5
xroots.append(bisection method(fP6,xleft,xright))
print("Root 4 between", xleft, "and", xright, "is x =", xroots[-1])
xleft = 0.5
xright = 0.75
xroots.append(bisection method(fP6,xleft,xright))
print("Root 5 between", xleft, "and", xright, "is x =",xroots[-1])
xleft = 0.75
xright = 1.
xroots.append(bisection method(fP6,xleft,xright))
print("Root 6 between", xleft, "and", xright, "is x =", xroots[-1])
```

Strategy 1: Bracket each root from visual analysis and use the bisection method for refinement

```
xroots = []
# Root 1
xleft = -1.
xright = -0.75
xroots.append(bisection method(fP6,xleft,xright))
print("Root 1 between", xleft, "and", xright, "is x =", xroots[-1])
x = -0.75
xright = -0.5
xroots.append(bisection method(fP6,xleft,xright))
print("Root 2 between", xleft, "and", xright, "is x =", xroots[-1])
xleft = -0.5
xright = 0.
xroots.append(bisection method(fP6,xleft,xright))
print("Root 3 between", xleft, "and", xright, "is x =", xroots[-1])
xleft = 0.
xright = 0.5
xroots.append(bisection method(fP6,xleft,xright))
print("Root 4 between", xleft, "and", xright, "is x =", xroots[-1])
xleft = 0.5
xright = 0.75
xroots.append(bisection method(fP6,xleft,xright))
print("Root 5 between", xleft, "and", xright, "is x =",xroots[-1])
xleft = 0.75
xright = 1.
xroots.append(bisection method(fP6,xleft,xright))
print("Root 6 between", xleft, "and", xright, "is x =", xroots[-1])
```

Strategy 1 is fairly fail-safe but requires significant manual pre-processing

Strategy 2:

- 1. Use one of the standard methods (e.g. Newton-Raphson) to find the first root x_1
- 2. Divide the polynomial by $(x-x_1)$
- 3. Apply Newton's method to the new polynomial to find x_2
- 4. Divide the polynomial by $(x-x_2)$ and repeat the above steps until all roots are found

Optional optimization:

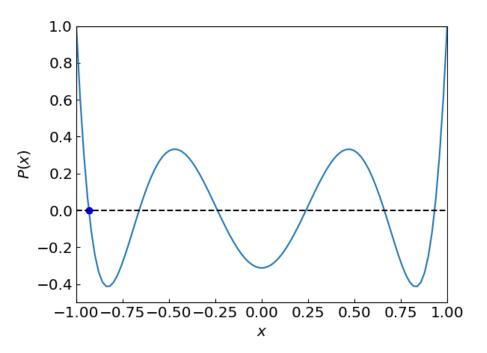

Refine the roots by applying Newton-Raphson method again to the original polynomial, using the tentative roots as initial guesses This helps to mitigate round-off error accumulation inherent in polynomial division

```
Using strategy 2, initial guess x_0 = -1
```

Try to go higher order? How high can we go?

Systems of non-linear equations

$$f_1(x_1, ..., x_N) = 0,$$

 $f_2(x_1, ..., x_N) = 0,$
...
 $f_N(x_1, ..., x_N) = 0$

References: Chapter 9.6 of *Numerical Recipes Third Edition* by W.H. Press et al.

Often, we need to solve a system of coupled non-linear equations, e.g.

$$f_1(x_1, ..., x_N) = 0,$$

$$f_2(x_1, ..., x_N) = 0,$$

...

$$f_N(x_1, ..., x_N) = 0$$

Vector notation: $\mathbf{f} = (f_1, ..., f_N)$ and $\mathbf{x} = (x_1, ..., x_N)$

 $\mathbf{f}(\mathbf{x}) = 0 \ .$

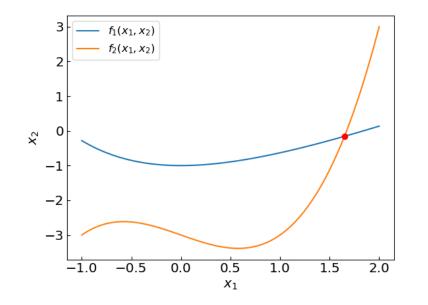

For example:

$$x + \exp(-x) - 2 - y = 0,$$

$$x^{3} - x - 3 - y = 0.$$

i.e.

$$f_1(x_1, x_2) = x_1 + \exp(-x_1) - 2 - x_2$$
$$f_2(x_1, x_2) = x_1^3 - x_1 - 3 - x_2$$

We have a system on non-linear equations f(x) = 0

Taylor expansion around the root x^* reads (multi-variate calculus)

 $f(x^*) \approx f(x) + J(x)(x^* - x)$ 1D: $f(x^*) \approx f(x) + f'(x)(x^* - x)$

 γc

J(x) is the Jacobian, i.e. a NxN matrix of derivatives evaluated at x:

$$J_{ij} = \frac{\partial f_i}{\partial x_j}$$

 $\mathbf{f}(\boldsymbol{x}^*) = \mathbf{0} \qquad \qquad \mathbf{J}(x)(x^* - x) \approx -f(x) \qquad \qquad \mathbf{x}^* \approx x - J^{-1}(x) f(x)$

The multi-dimensional **Newton's method** is an iterative procedure:

$$x_{n+1} = x_n - \boldsymbol{J^{-1}}(\boldsymbol{x_n}) \boldsymbol{f}(\boldsymbol{x_n})$$

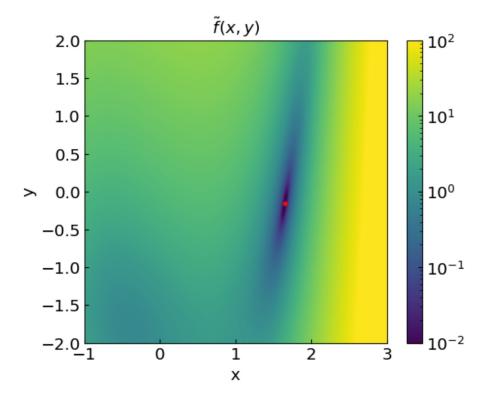

In 1D reduces to Newton-Raphson: $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$

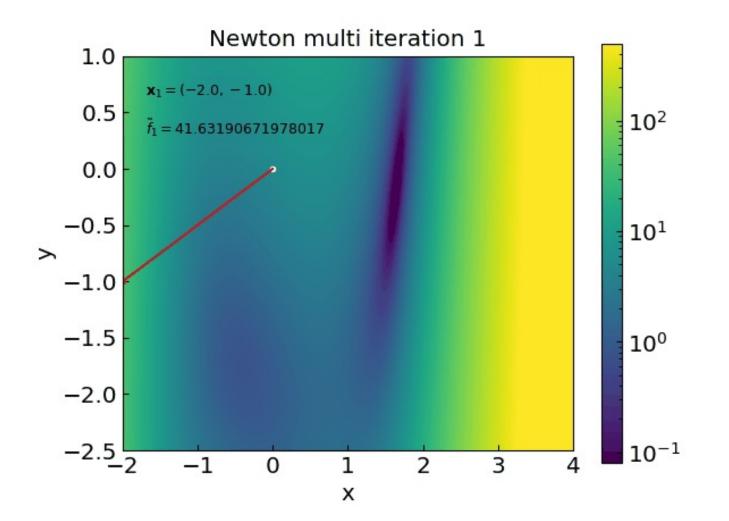

```
def newton method multi(
                                                                        3
                                                                                  f_1(x_1, x_2)

```

Introduce an objective function

$$\tilde{f}(\mathbf{x}) = \frac{\mathbf{f}(\mathbf{x}) \cdot \mathbf{f}(\mathbf{x})}{2}$$

Its value is equal to zero (minimized) at the root

Broyden method is a multi-dimensional generalization of the secant method

$$\text{Secant method (1D):} \quad x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} \qquad \text{with} \qquad f'(x_n) \simeq \frac{f(x_n) - f(x_{n-1})}{x_n - x_{n-1}}$$

Broyden method: $\mathbf{x}_{n+1} = \mathbf{x}_n - J^{-1}(\mathbf{x}_n) \mathbf{f}(\mathbf{x}_n)$ with $J(\mathbf{x}_n) (\mathbf{x}_n - \mathbf{x}_{n-1}) \simeq \mathbf{f}(\mathbf{x}_n) - \mathbf{f}(\mathbf{x}_{n-1})$

The solution for $J(x_n)$ is not unique

Broyden:
$$\mathbf{J}_n = \mathbf{J}_{n-1} + \frac{\Delta \mathbf{f}_n - \mathbf{J}_{n-1} \Delta \mathbf{x}_n}{\|\Delta \mathbf{x}_n\|^2} \Delta \mathbf{x}_n^{\mathrm{T}}$$
with $\mathbf{f}_n = \mathbf{f}(\mathbf{x}_n),$ $\Delta \mathbf{f}_n = \mathbf{f}_n - \mathbf{f}_n - \mathbf{f}_n$

Initial Jacobian J_0 :

- Calculate the Jacobian $J(x_0)$
- Initialize with Identity matrix $J(x_0) = I$ •

$$egin{aligned} \mathbf{f}_n &= \mathbf{f}(\mathbf{x}_n), \ \Delta \mathbf{x}_n &= \mathbf{x}_n - \mathbf{x}_{n-1}, \ \Delta \mathbf{f}_n &= \mathbf{f}_n - \mathbf{f}_{n-1}, \end{aligned}$$

requires derivative but more accurate no derivative but can converge slower

Broyden method (direct)

```
3
# Direct implementation of Broyden's method
# (using matrix inversion at each step)
def broyden method direct(
                                                                       2

return X

Broyden method: avoid matrix inversion

$$\mathbf{J}_n = \mathbf{J}_{n-1} + rac{\Delta \mathbf{f}_n - \mathbf{J}_{n-1} \Delta \mathbf{x}_n}{\|\Delta \mathbf{x}_n\|^2} \Delta \mathbf{x}_n^{\mathrm{T}}$$

Sherman-Morrison formula:

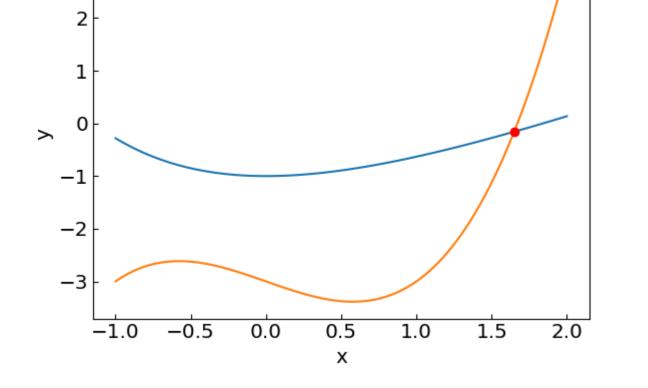

$$\mathbf{J}_n^{-1} = \mathbf{J}_{n-1}^{-1} + rac{\Delta \mathbf{x}_n - \mathbf{J}_{n-1}^{-1} \Delta \mathbf{f}_n}{\Delta \mathbf{x}_n^{\mathrm{T}} \mathbf{J}_{n-1}^{-1} \Delta \mathbf{f}_n} \Delta \mathbf{x}_n^{\mathrm{T}} \mathbf{J}_{n-1}^{-1}$$

Update the inverse Jacobian directly!

Broyden method (Sherman-Morrison)

```
def broyden method(
    f,
    x0,
    accuracy=1e-8,
    max_iterations=100):
    global last_broyden_iterations
    last_broyden_iterations = 0
   x = x0
    n = x0.shape[0]
    Jinv = np.eye(n)
    for i in range(max_iterations):
        last_broyden_iterations += 1
       f val = f(x)
        delta = -Jinv.dot(f val)
        x = x + delta
        if np.linalg.norm(delta, ord=2) < accuracy:</pre>
            return x
       f new = f(x)
        df = f new - f val
        dx = delta
        Jinv = Jinv + np.outer(dx - Jinv.dot(df), dx.T.dot(Jinv))
        / np.dot(dx.T, Jinv.dot(df))
```

return x

Iteration: 54
x = [1.64998819 -0.15795963]
f = [2.8255176e-14 -3.8877096e-10]
|f| = 7.557143001803891e-20

3

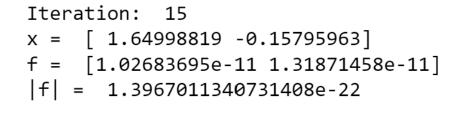

Broyden method converges somewhat slower (e.g. 54 vs 12 iterations in our example) but:

- Does not involve the calculation of Jacobian
- Does not involve matrix inversion

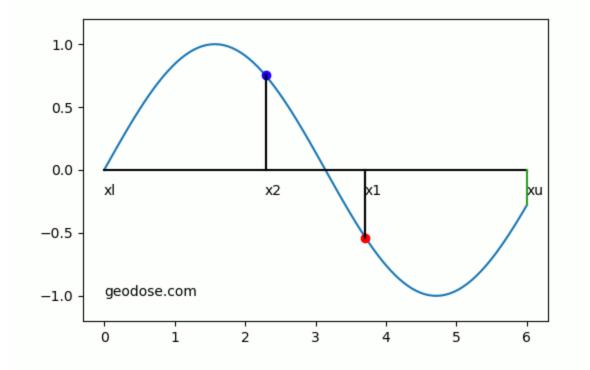

Possible refinement: improve the initial estimate for the Jacobian

```
Iteration: 54
x = [ 1.64998819 -0.15795963]
f = [ 2.8255176e-14 -3.8877096e-10]
|f| = 7.557143001803891e-20
```

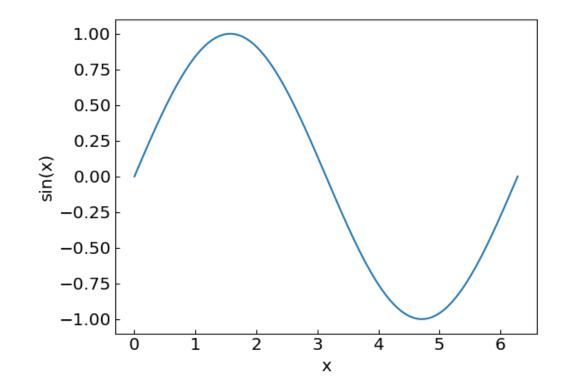

Function minimization/maximization

References: Chapter 6.4 of *Computational Physics* by Mark Newman Chapter 10 of *Numerical Recipes Third Edition* by W.H. Press et al. Often we are interested to find the minimum of a function (e.g. energy minimization)

Consider the minimum of f(x) = sin(x) on interval $0..2\pi$

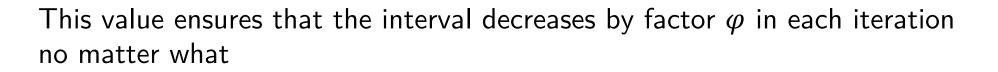

Golden section search

1. Bracket the minimum x_{min} in (a,b)

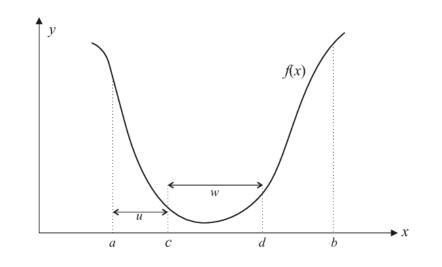

2. Take c = b – (b-a)/
$$\varphi$$
 and d = a + (b-a)/ φ

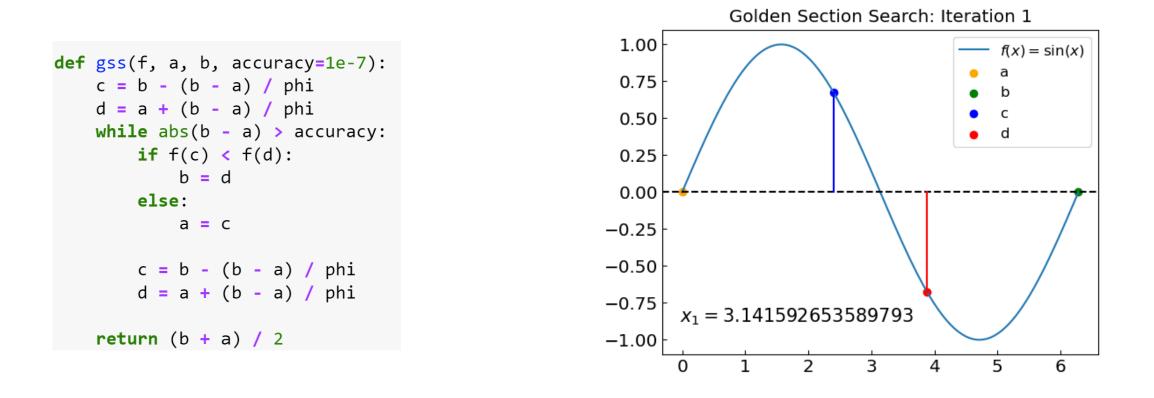

- 3. If f(c) < f(d), take b = d as new right endpoint
- 4. Otherwise, take a = c as new left endpoint
- 5. Repeat over the new, smaller interval (a,b) until the desired accuracy is reached

$$\varphi = \frac{1+\sqrt{5}}{2} = 1.618 \dots$$
 is the **golden ratio**

The method works when the function is unimodal

The minimum of sin(x) over the interval (0.0 , 6.283185307179586) is 4.712388990891052

To search for a maximum of f(x) look for a minimum of -f(x)

The extremum of f(x) is the root of the derivative, f'(x) = 0

Simply apply Newton-Raphson method (or one other standard methods) for finding the root of f'(x)

$$x_{n+1} = x_n - \frac{f'(x_n)}{f''(x_n)}$$

 $f''(x) > 0, \quad o \qquad ext{minimum}$ $f''(x) < 0, \quad o \qquad ext{maximum}$

```
def newton_extremum(f, df, d2f, x0, accuracy=1e-7, max_iterations=100):
    xprev = xnew = x0
    for i in range(max_iterations):
        xnew = xprev - df(xprev) / d2f(xprev)
        if (abs(xnew-xprev) < accuracy):
            return xnew
            xprev = xnew
            xprev = xnew
            return xnew</pre>
```

An extremum of sin(x) using Newton's method starting from x0 = 5.0 is (0.0, 6.283185307179586) is 4.71238898038469

Gradient descent method

Replace, f''(x) by a descent factor $1/\gamma_n$

$$x_{n+1} = x_n - \gamma_n f'(x_n)$$

 $\gamma_n > 0$ (minimum) $\gamma_n < 0$ (minimum)

```
def gradient_descent(f, df, x0, gam = 0.01, accuracy=1e-7, max_iterations=100):
    xprev = x0
    for i in range(max_iterations):
        xnew = xprev - gam * df(xprev)
        if (abs(xnew-xprev) < accuracy):
            return xnew
            xprev2 = xprev
            xprev = xnew
            return xnew</pre>
```

Freedom in choosing γ_n

Can be generalized to multi-variable function $F(x_1, x_2, ...)$ final project idea(?)

$$\mathbf{x}_{n+1} = \mathbf{x}_n - \gamma_n \nabla F(\mathbf{x}_n)$$
