QCD under extreme conditions

From 2015 US Nuclear Long Range Plan

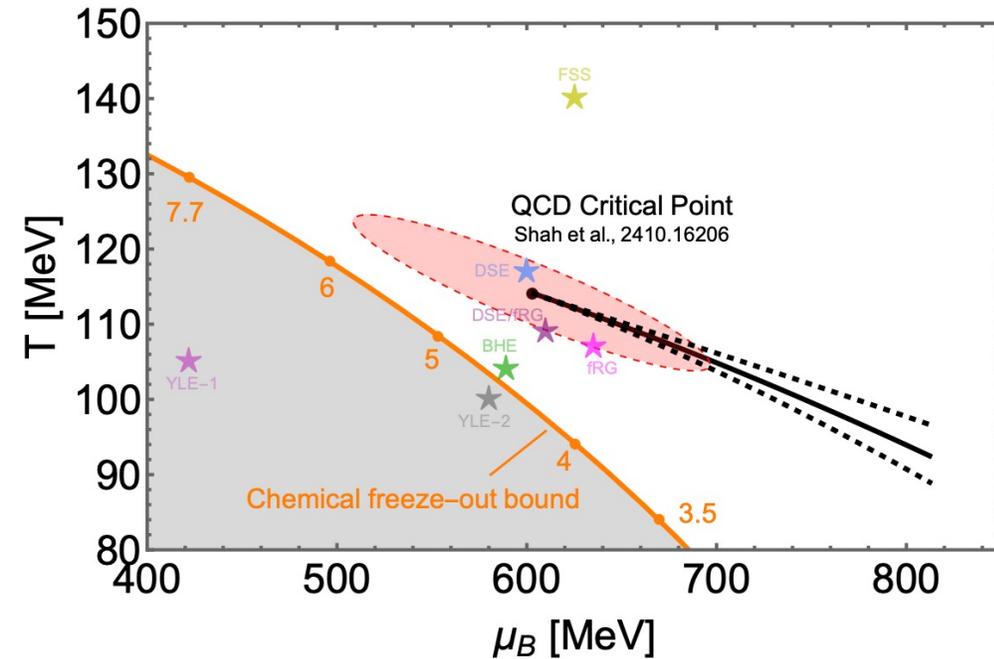

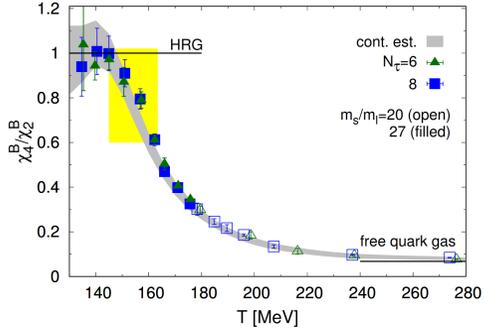

Figure from H. Shah et al., PRC 113, L012201 (2026)

- One of key questions: *Is there a QCD critical point and how to find it?*
- Several predictions place it in the vicinity of the freeze-out curve in heavy-ion collisions
- Probe with measurements of proton cumulants at RHIC

Theory vs experiment

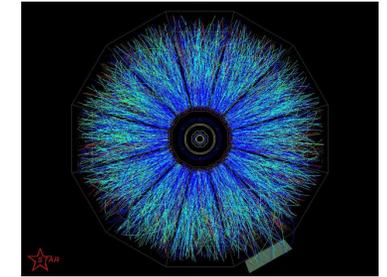

guidance from theory (e.g. lattice)

experiment (the real thing)

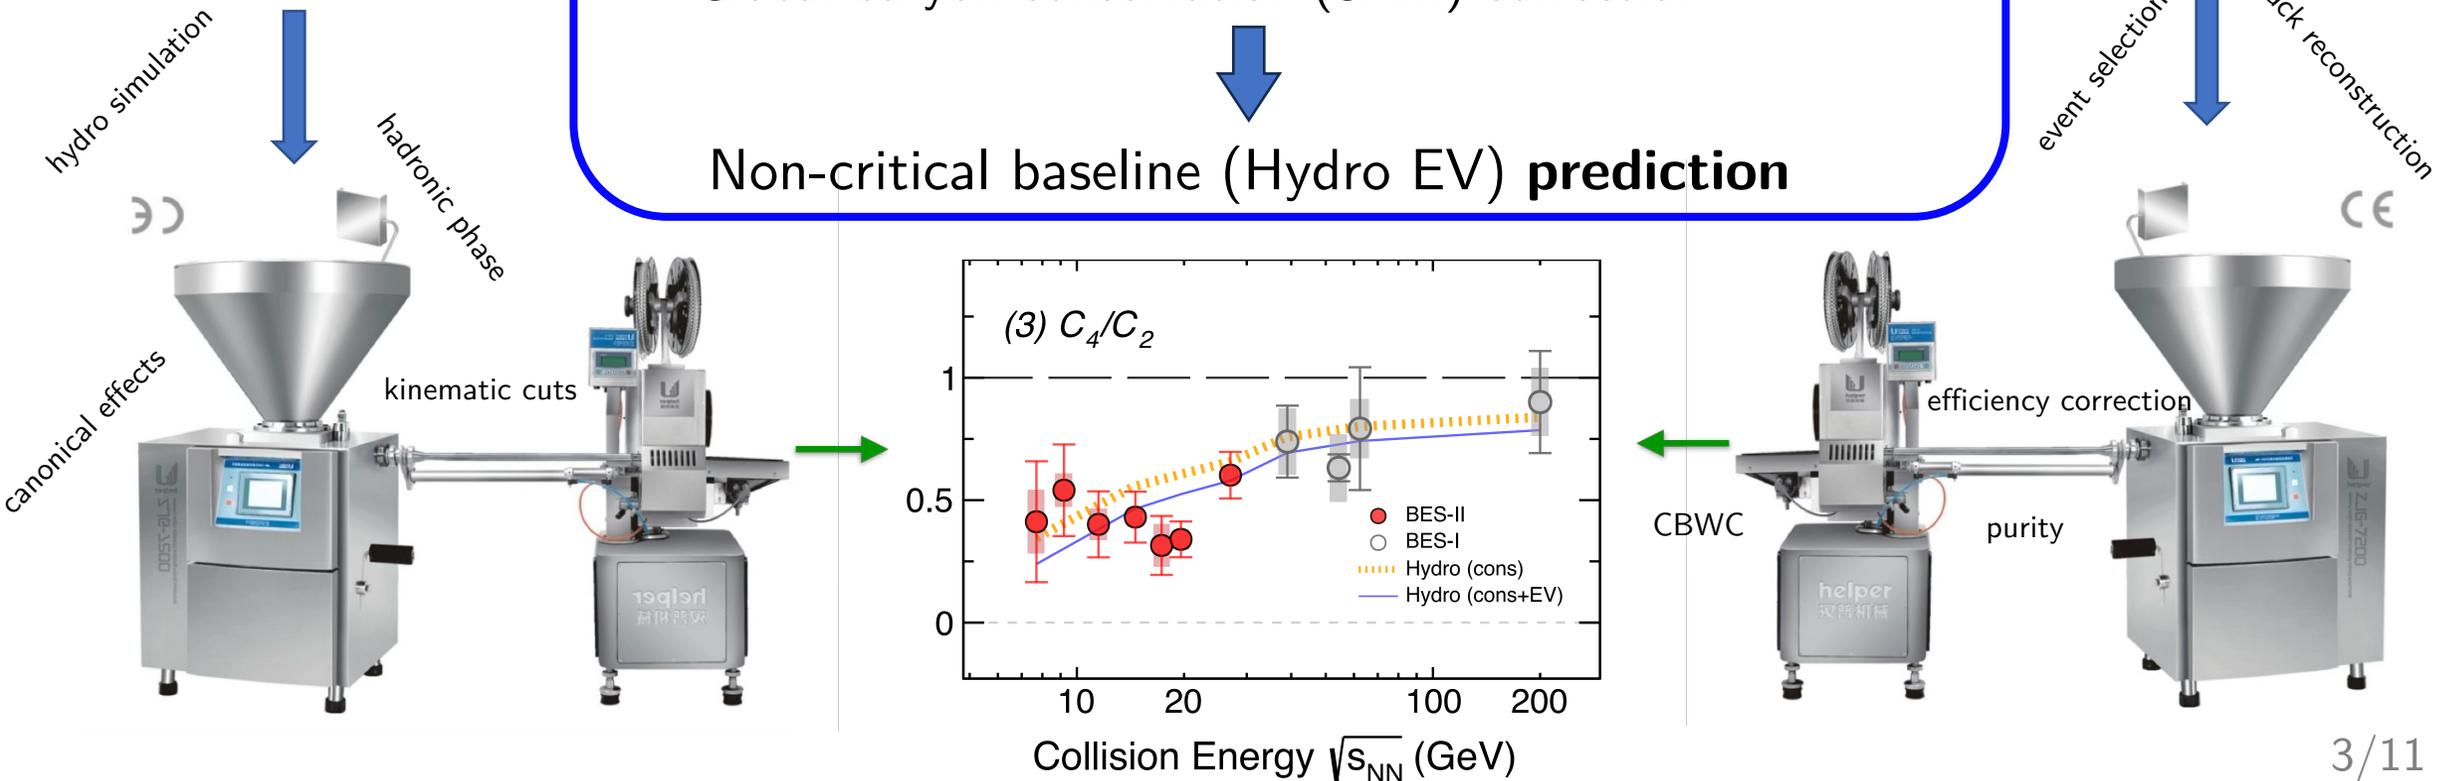

This was done in [VV, V. Koch, C. Shen, Phys. Rev. C 105, 014904 (2022)]

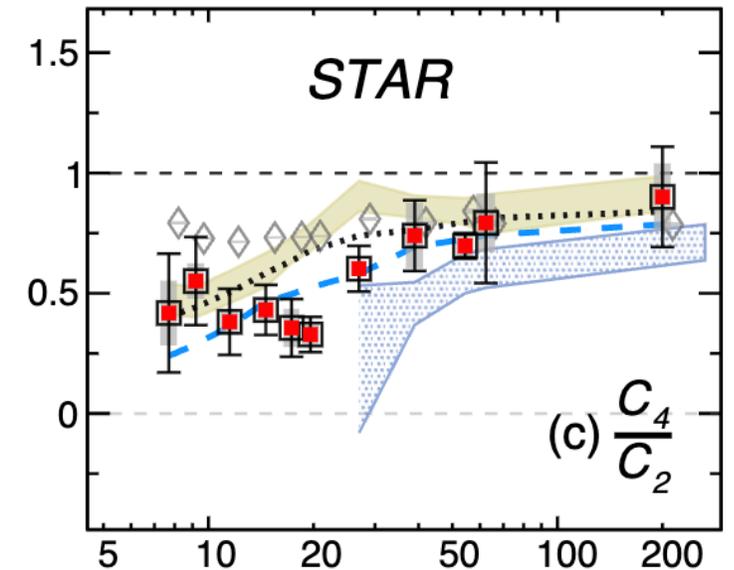

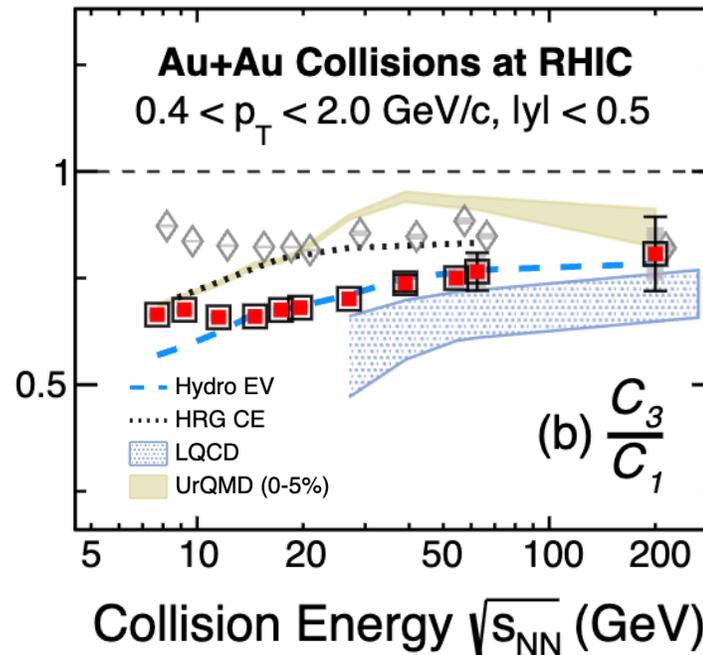

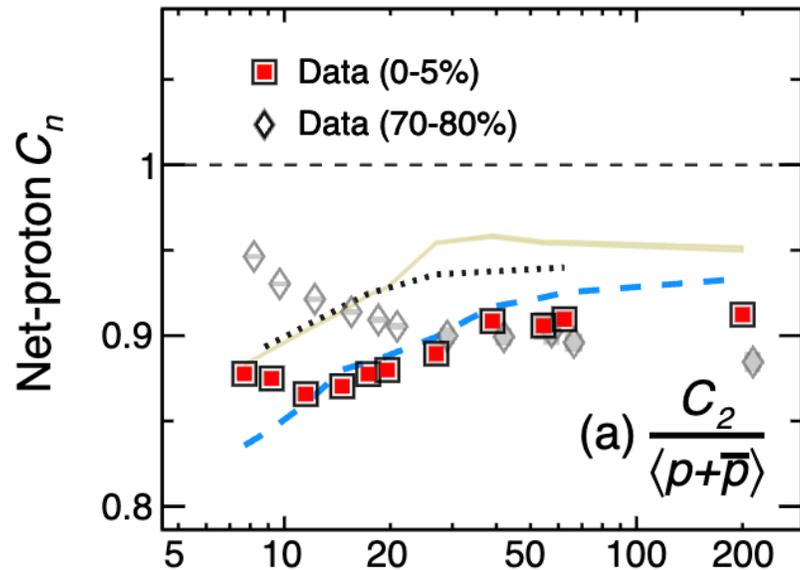

- Full hydro simulation
- Lattice QCD-like baryon susceptibilities (interacting HRG)
- Experimental kinematic cuts
- Global baryon conservation (SAM) correction

Non-critical baseline (Hydro EV) prediction

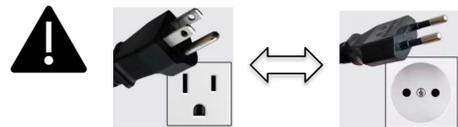

Net-proton cumulant ratios

STAR, PRL 135, 142301 (2025)

Hydro EV: [VV, V. Koch, C. Shen, Phys. Rev. C 105, 014904 \(2022\)](#)

HRG CE: [Braun-Munzinger et al., Nucl. Phys. A 1008, 122141 \(2021\)](#)

From M. Arslandok, QM2025

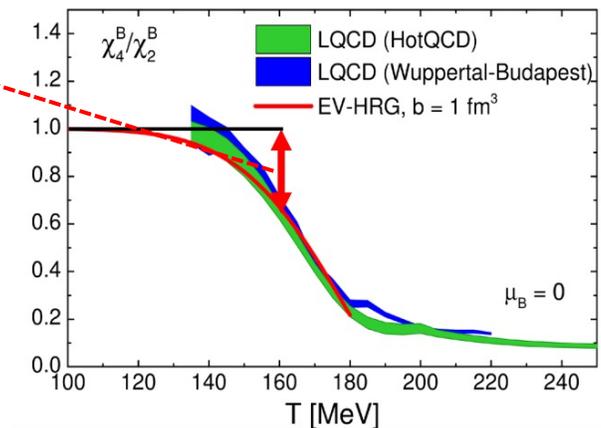

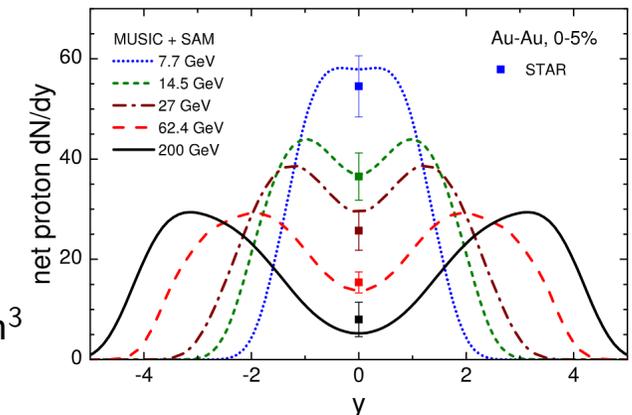

Fair agreement with the baseline above $\sqrt{s_{NN}} \sim 10 - 20$ GeV

Can we learn more about the EoS?

Hydro EV description

VV, V. Koch, C. Shen, Phys. Rev. C 105, 014904 (2022)

- (3+1)-D viscous hydrodynamics evolution (MUSIC-3.0)
 - Collision geometry-based 3D initial state [Shen, Alzhrani, PRC 102, 014909 (2020)]
 - Crossover equation of state based on lattice QCD [Monnai, Schenke, Shen, Phys. Rev. C 100, 024907 (2019)]
- Non-critical contributions computed at particlization ($\epsilon_{sw} = 0.26 \text{ GeV}/\text{fm}^3$)
 - Lattice QCD-like baryon number distribution (χ_n^B) via **excluded volume** $b = 1 \text{ fm}^3$ [VV, V. Koch, Phys. Rev. C 103, 044903 (2021)]
 - Kinematic cuts via Cooper-Frye formula
- Exact global baryon conservation via correction step at the end
 - Subensemble acceptance method (SAM-2.0) (analytic) [VV, Phys. Rev. C 105, 014903 (2022)]
- **Included:** baryon conservation, repulsion, kinematical cuts
- However, effects mix together, are difficult to disentangle, and require complex numerical calculation each time

Reevaluate using density-density correlator

Density-density correlator of net baryon number (uniform system) [VV, Phys. Rev. C 110, L061902 (2024)]

$$C_2(\mathbf{r}_1, \mathbf{r}_2) = \chi_2 \delta(\mathbf{r}_1 - \mathbf{r}_2) - \frac{\chi_2}{V}$$

local fluctuations (EoS) **balancing contribution (e.g. baryon conservation)**

Generalized: Non-conserved quantity X (e.g. protons) correlated to B on Cooper-Frye surface

$$C_2^X(x_1, x_2) = \chi_2^X(x_1) \delta(x_1 - x_2) - \frac{\chi_{11}^{XB}(x_1) \chi_{11}^{XB}(x_2)}{\kappa_2^{B, \text{gce}}}$$

local fluctuations (self-correlations + two-particle) **balancing contribution (e.g. baryon conservation)**

$$\kappa_2^{B, \text{gce}} = \int_{\sigma(x)} dV(x) \chi_2^B(x)$$

Cooper-Frye (CF) integral **CF volume element**

$$dV(x) = d\sigma_\mu(x) u^\mu(x)$$

Ingredients and differences to Hydro-EV

- Baryon conservation (total net baryon number does not fluctuate) enforced straight away
- EoS effects encoded in χ_2 (not restricted to excluded volume repulsion)
- Both effects clearly disentangled so far

Consider fluctuations of positive baryons ($X = B^+$)

- Parametrize GCE baryon correlations by scaled variance ω_+
- No correlations among baryons and antibaryons
- Neglect variations in ω_+ along freeze-out hypersurface

$\omega_+ < 1$ $\omega_+ = 1$ $\omega_+ > 1$
repulsion **Poisson** **attraction**

$$\chi_2^X(x) = \omega_+ \langle n_+ \rangle(x)$$

$$\chi_{11}^{XB}(x) = \omega_+ \langle n_+ \rangle(x)$$

$$\kappa_2^{B,gce} = \omega_+ \langle N_+ \rangle + \omega_- \langle N_- \rangle$$

- Kinematic acceptance + efficiency factor $p(x)$: probability to detect baryon emitted from x

Density-density correlator becomes

$$C_2^X(x_1, x_2) = p(x_1) \langle n_+ \rangle(x_1) \delta(x_1 - x_2) + [p(x_1)]^2 (\omega_+ - 1) \langle n_+ \rangle(x_1) \delta(x_1 - x_2) - \frac{(\omega_+)^2 p(x_1) \langle n_+ \rangle(x_1) p(x_2) \langle n_+ \rangle(x_2)}{\omega_+ \langle N_+ \rangle + \omega_- \langle N_- \rangle}$$

self-correlation (Poisson)

local two-particle correlations

balancing contribution from baryon conservation

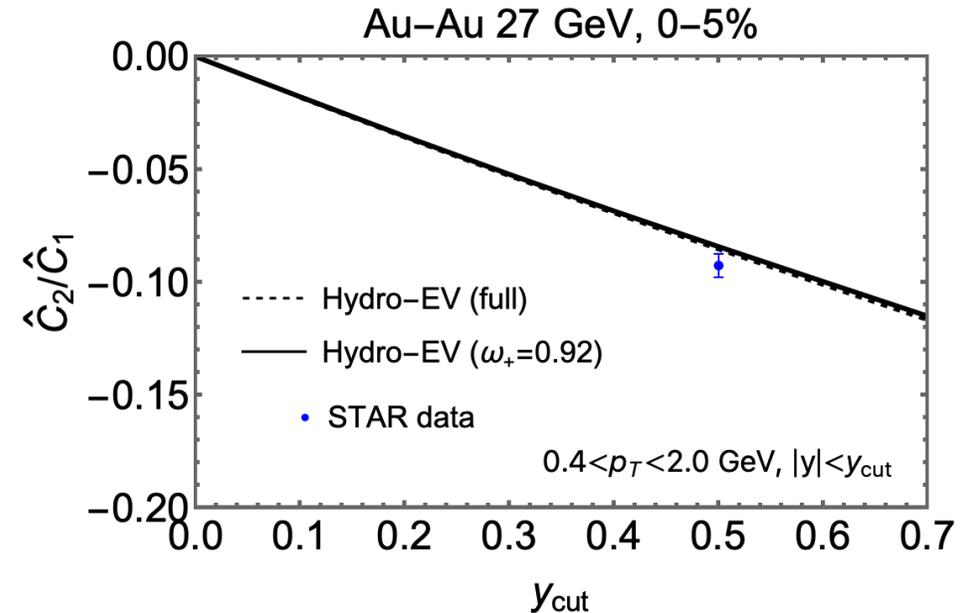

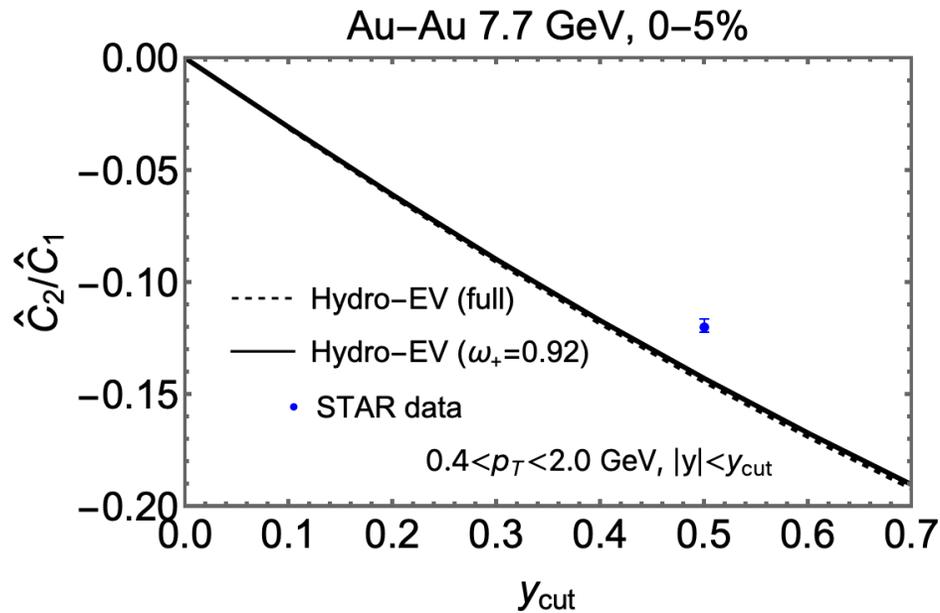

Integrating the correlator yields measurable proton variance

$$\frac{\kappa_2[p]}{\langle N_p \rangle} = 1 + (\omega_+ - 1) \frac{\langle p^2 \rangle_n}{\langle p \rangle_n} - (\omega_+)^2 \langle p \rangle_n \frac{\langle N_+ \rangle}{\omega_+ \langle N_+ \rangle + \omega_- \langle N_- \rangle}$$

Simplified proton variance

$$\frac{\kappa_2[p]}{\langle N_p \rangle} - 1 \approx (\omega_+ - 1) \frac{\langle p^2 \rangle_n}{\langle p \rangle_n} - \omega_+ \langle p \rangle_n \frac{\langle N_+ \rangle}{\langle N_+ \rangle + \langle N_- \rangle}$$

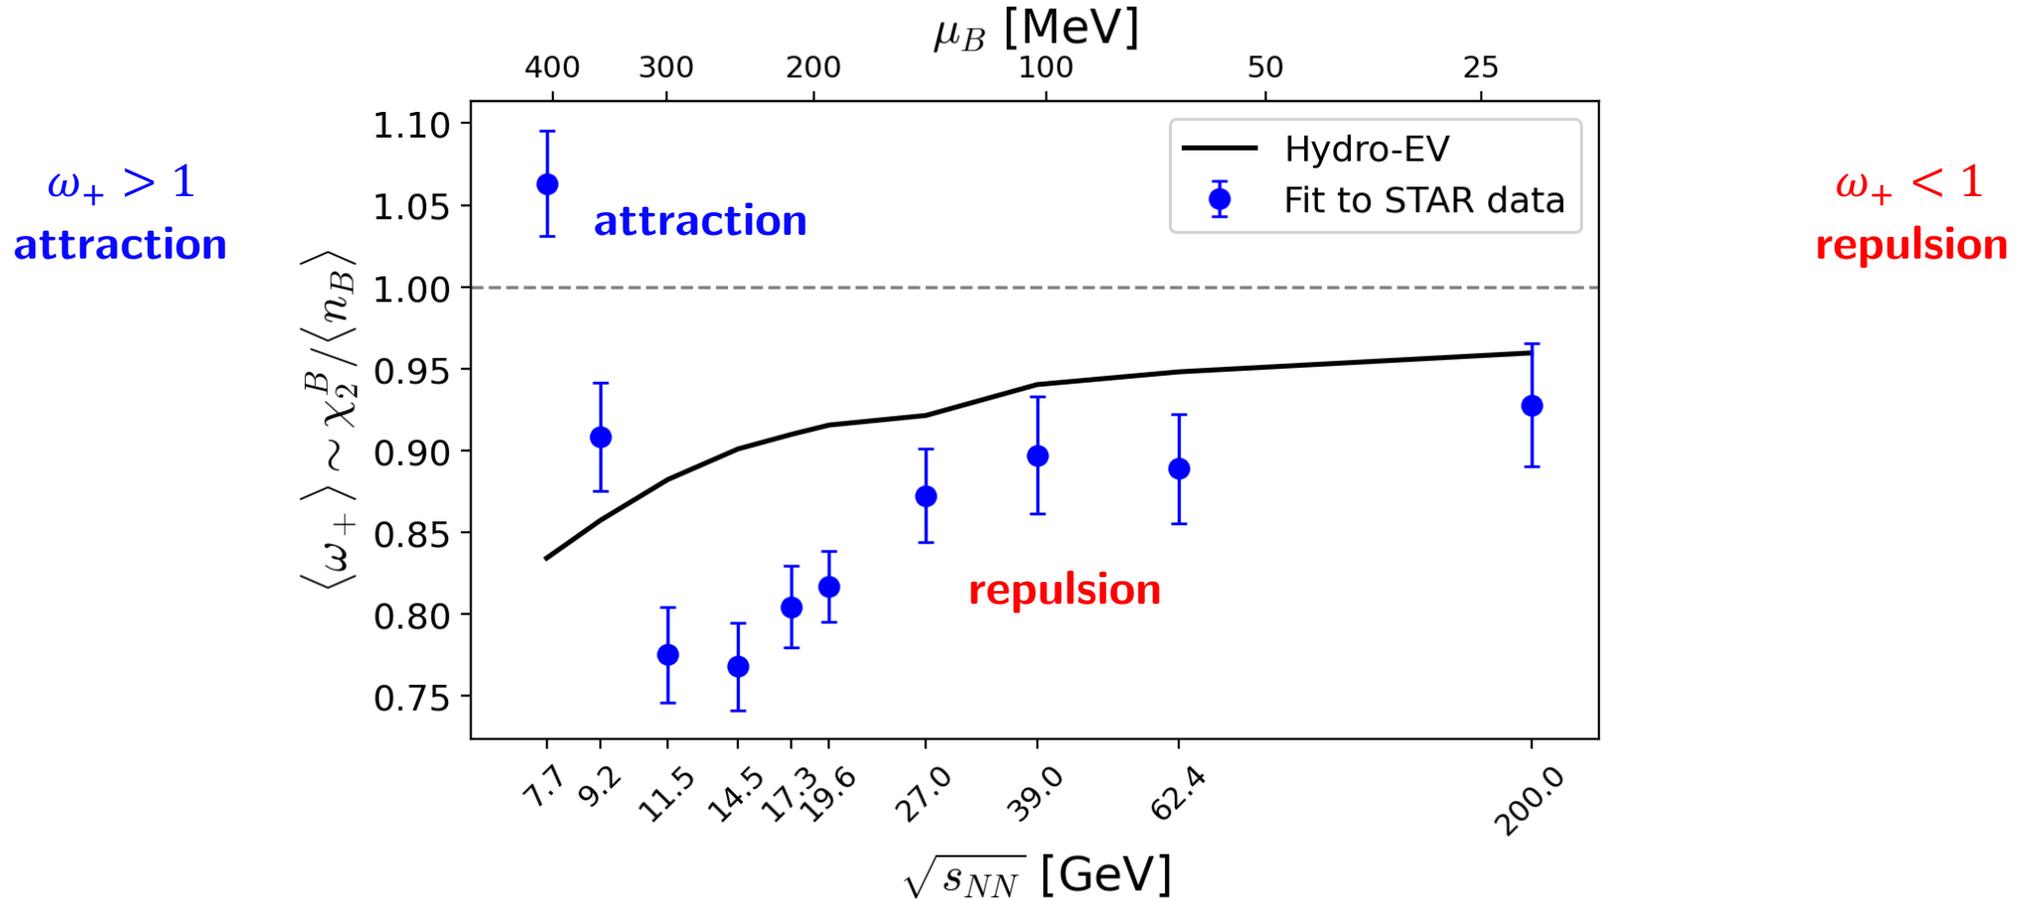

EoS acceptance (hydro) baryon (proton) fraction

Simplified expression is in excellent agreement with full numerical Hydro-EV calculation

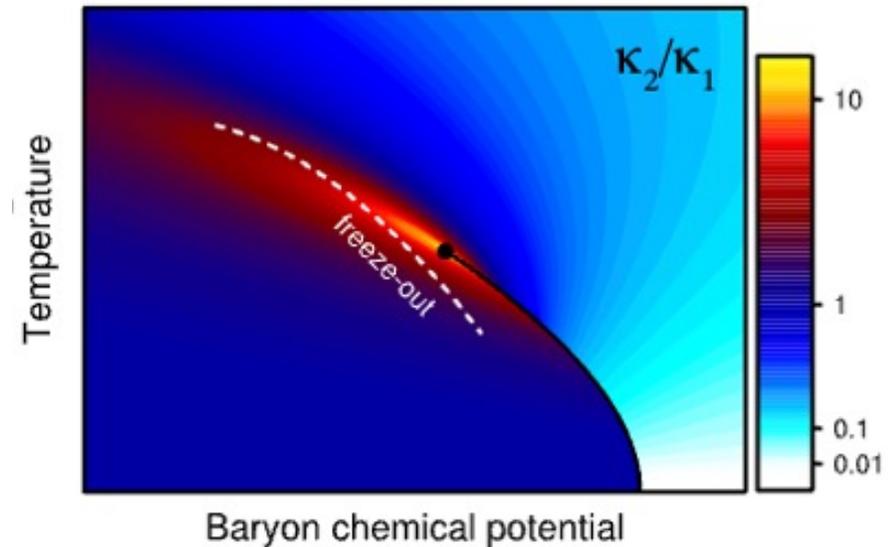

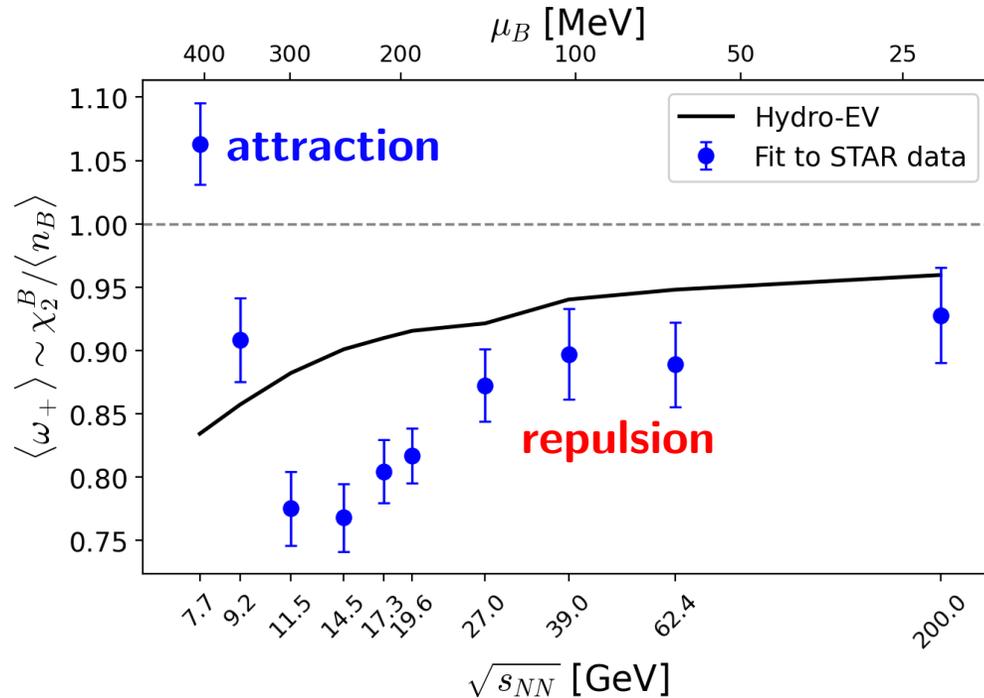

Now have freedom to vary ω_+ and constrain using data

Extracting scaled variance from data

Change of trend around 14 GeV from **repulsion** to **attraction** as $\sqrt{s_{NN}}$ is decreased

Attraction vs repulsion and the CP

VV, Anchishkin, Gorenstein, Poberezhnyuk, PRC 92, 054901 (2015)

Interplay of attraction and repulsion is typical for systems with a **critical point**

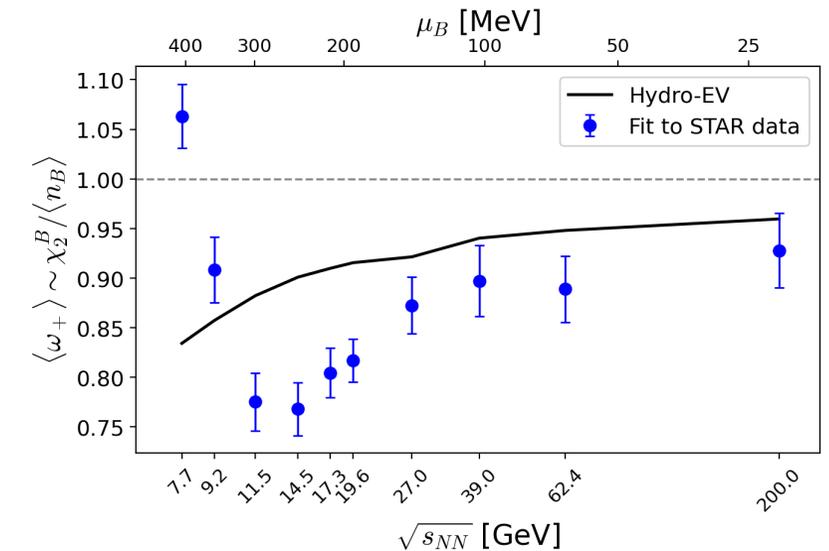

Caveats:

- Local conservation* not included \rightarrow would require more attraction/less repulsion
- Neglects volume fluctuations (STAR data are corrected with CBWC**)
- No hadronic phase; antiproton puzzle*** not resolved
- Assumes hydro validity; additional tests with acceptance dependence of cumulants***

*Parra et al., PRL 135, 242302 (2025); **Friman, Koch, arXiv:2511.11869; ***Bzdak, Koch, VV, PRC 112, 024901 (2025)

- Proton cumulants in heavy-ion collisions are complex observables sensitive to underlying QCD dynamics
- Density correlations approach simplifies hydrodynamical description of fluctuations and disentangles EoS from kinematical and conservation effects
- Analysis of RHIC-BES-II data indicate a switch from baryon repulsion to attraction around $\sqrt{s_{NN}} \sim 15$ GeV

Outlook:

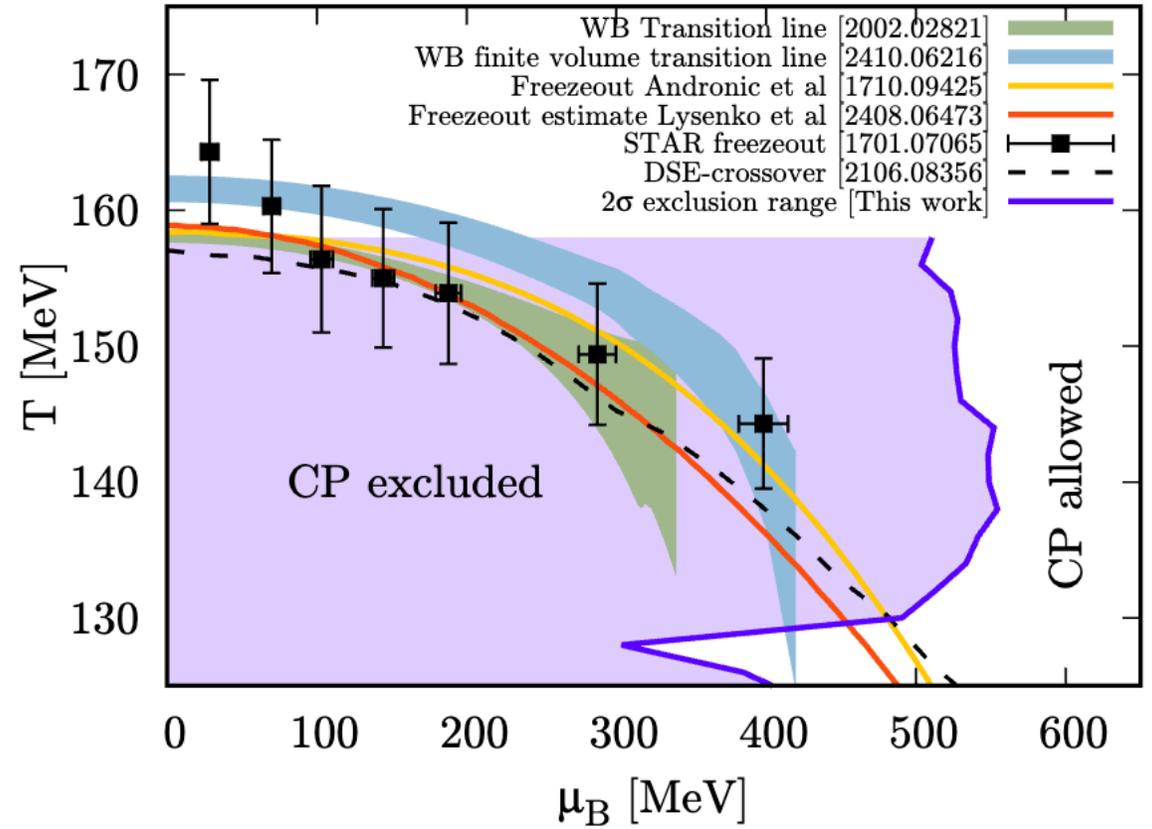

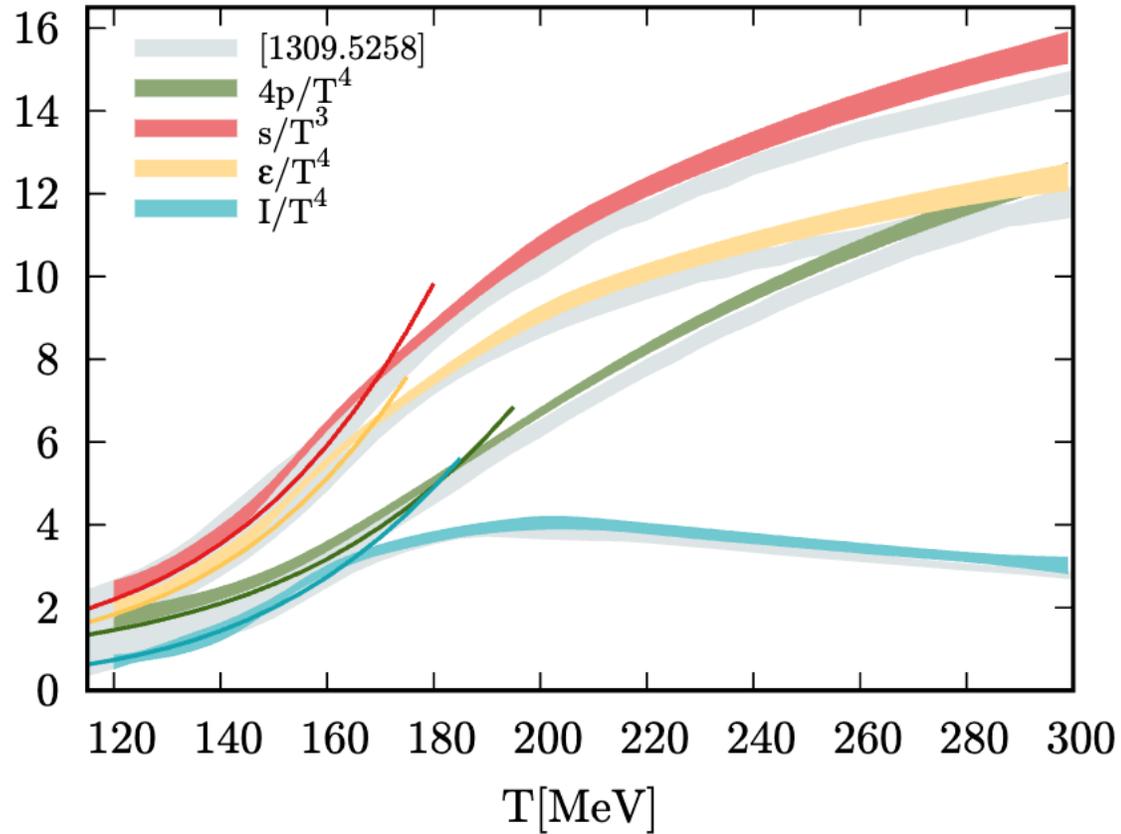

- High-order (factorial) cumulants
- Acceptance dependence and other observables
- Antiprotons

$$\frac{\kappa_2[p]}{\langle N_p \rangle} - 1 \approx (\omega_+ - 1) \frac{\langle p^2 \rangle_n}{\langle p \rangle_n} - \omega_+ \langle p \rangle_n \frac{\langle N_+ \rangle}{\langle N_+ \rangle + \langle N_- \rangle}$$

Thanks for your attention!

New constraints from lattice QCD

Event-by-event fluctuations and statistical mechanics

Cumulant generating function

$$K_N(t) = \ln \langle e^{tN} \rangle = \sum_{n=1}^{\infty} \kappa_n \frac{t^n}{n!}$$

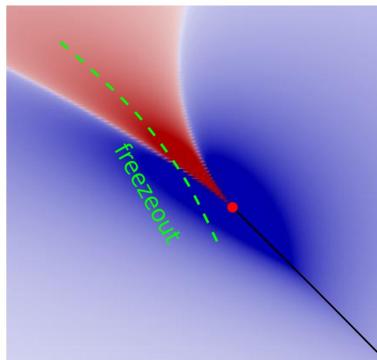

$$\kappa_n \propto \frac{\partial^n (\ln Z^{\text{gce}})}{\partial \mu^n}$$

Grand partition function

$$\ln Z^{\text{gce}}(T, V, \mu) = \ln \left[\sum_N e^{\mu N/T} Z^{\text{ce}}(T, V, N) \right]$$

Cumulants measure chemical potential derivatives of the (QCD) equation of state

- **(QCD) critical point:** large correlation length and fluctuations

M. Stephanov, PRL '09, '11
Energy scans at RHIC (STAR)
and CERN-SPS (NA61/SHINE)

$$\kappa_2 \sim \xi^2, \quad \kappa_3 \sim \xi^{4.5}, \quad \kappa_4 \sim \xi^7$$

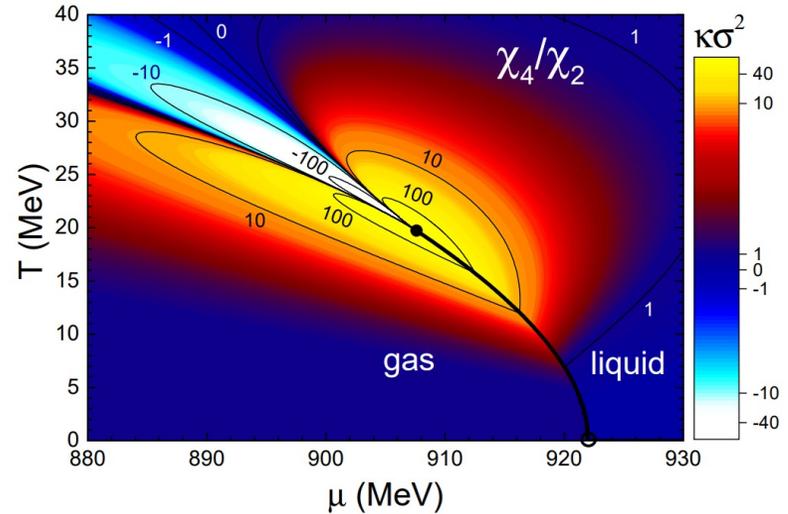

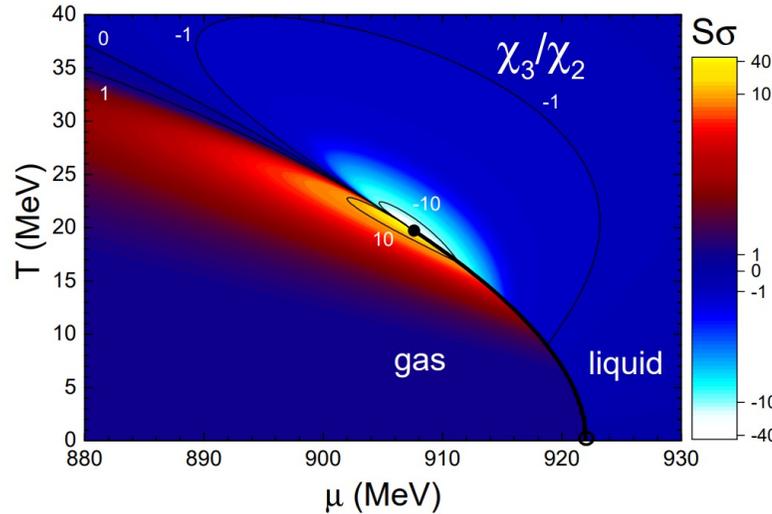

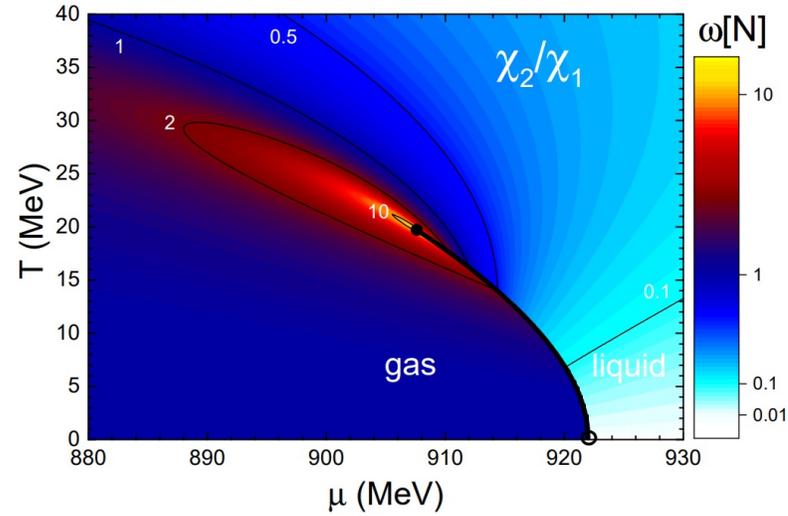

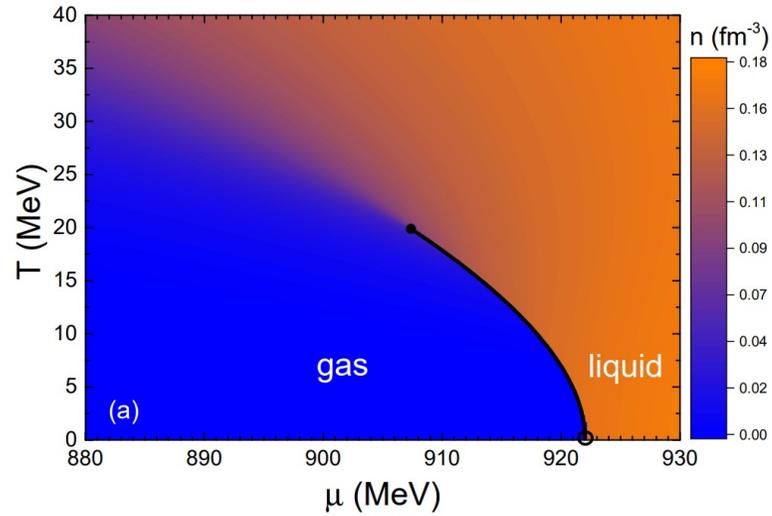

$$\xi \rightarrow \infty$$

Looking for enhanced fluctuations
and non-monotonocities

Example: (Nuclear) Liquid-gas transition

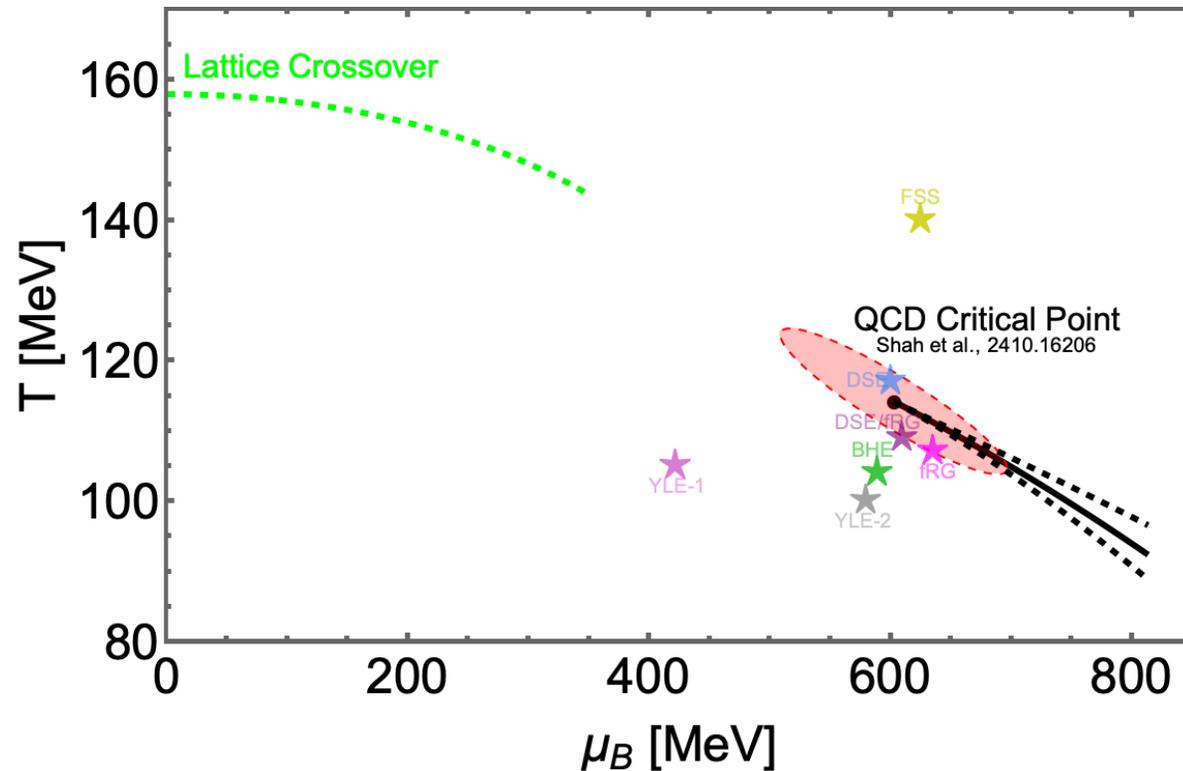

Critical opalescence

$$\langle N^2 \rangle - \langle N \rangle^2 \sim \langle N \rangle \sim 10^{23}$$

in equilibrium

Critical point estimates

Critical point estimate at $O(\mu_B^2)$:

$$T_c = 114 \pm 7 \text{ MeV}, \quad \mu_B = 602 \pm 62 \text{ MeV}$$

Estimates from recent literature:

YLE-1: D.A. Clarke et al. (Bielefeld-Parma), arXiv:2405.10196

YLE-2: G. Basar, PRC 110, 015203 (2024)

BHE: M. Hippert et al., arXiv:2309.00579

fRG: W-J. Fu et al., PRD 101, 054032 (2020)

DSE/fRG: Gao, Pawłowski., PLB 820, 136584 (2021)

DSE: P.J. Gunkel et al., PRD 104, 052022 (2021)

FSS: A. Sorensen et al., arXiv:2405.10278

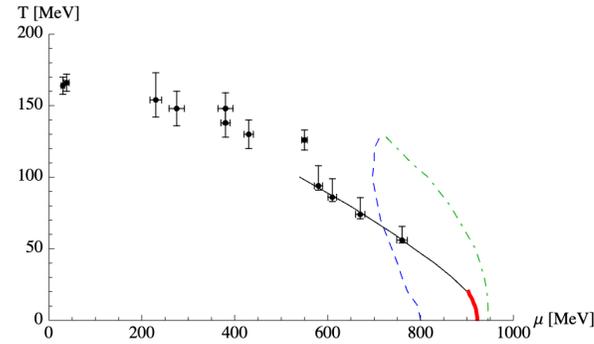

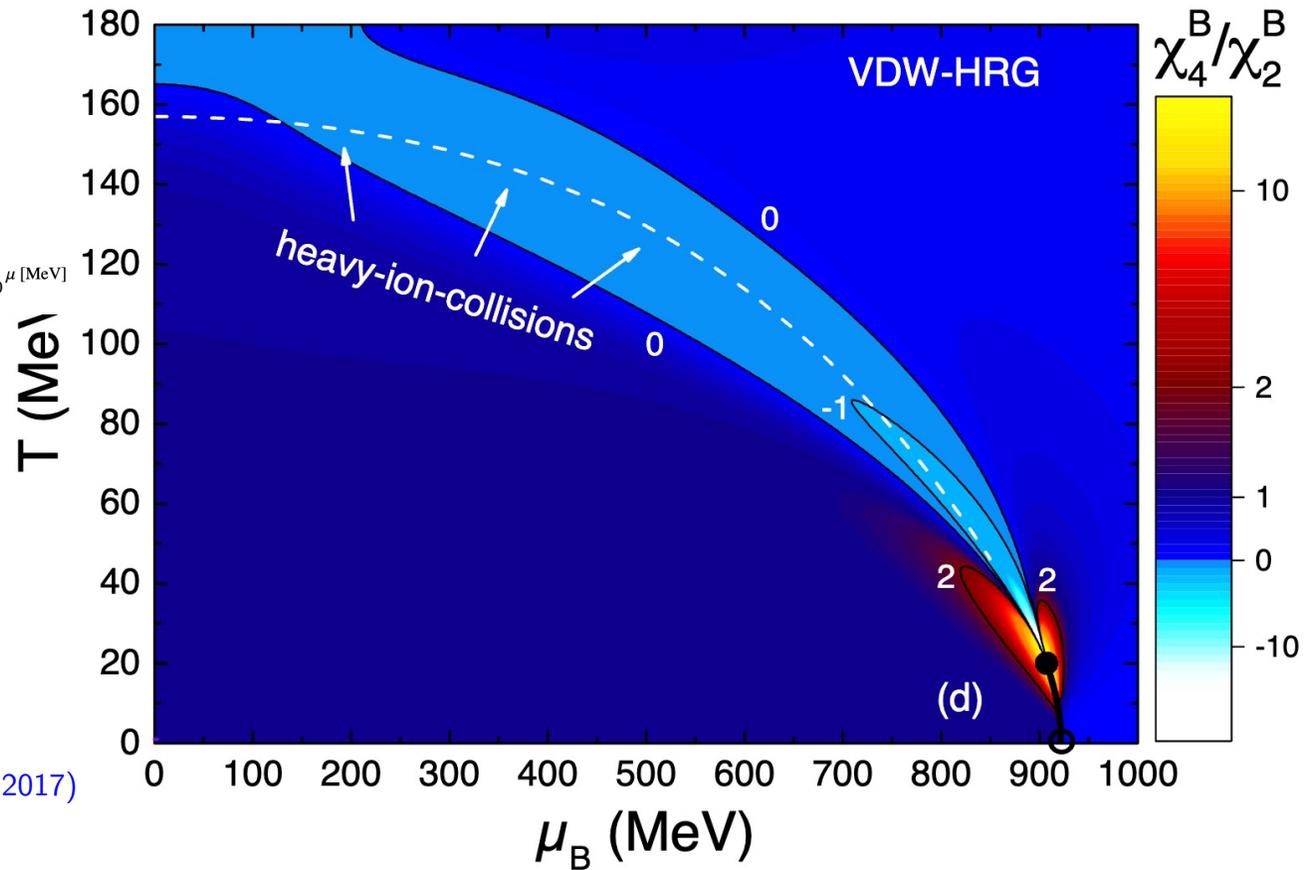

Optimist's view: Different estimates converge onto the same region because QCD CP is likely there

Pessimist's view: Different estimates converge onto the same region because it's the closest not yet ruled out by LQCD

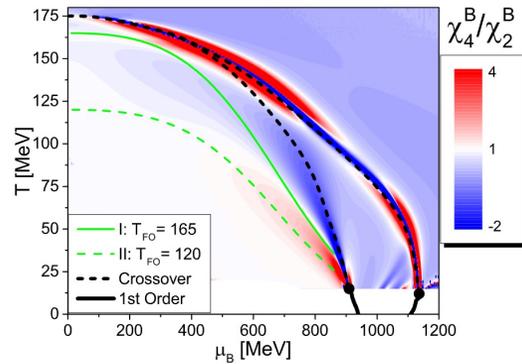

“...experimental measurements are essential to determine whether a QCD critical point exists.”

Interplay with nuclear liquid-gas transition

HRG with attractive and repulsive interactions among baryons

Mukherjee, Steinheimer, Schramm, PRC (2017)

VV, Gorenstein, Stoecker, Phys. Rev. Lett. 118, 182301 (2017)

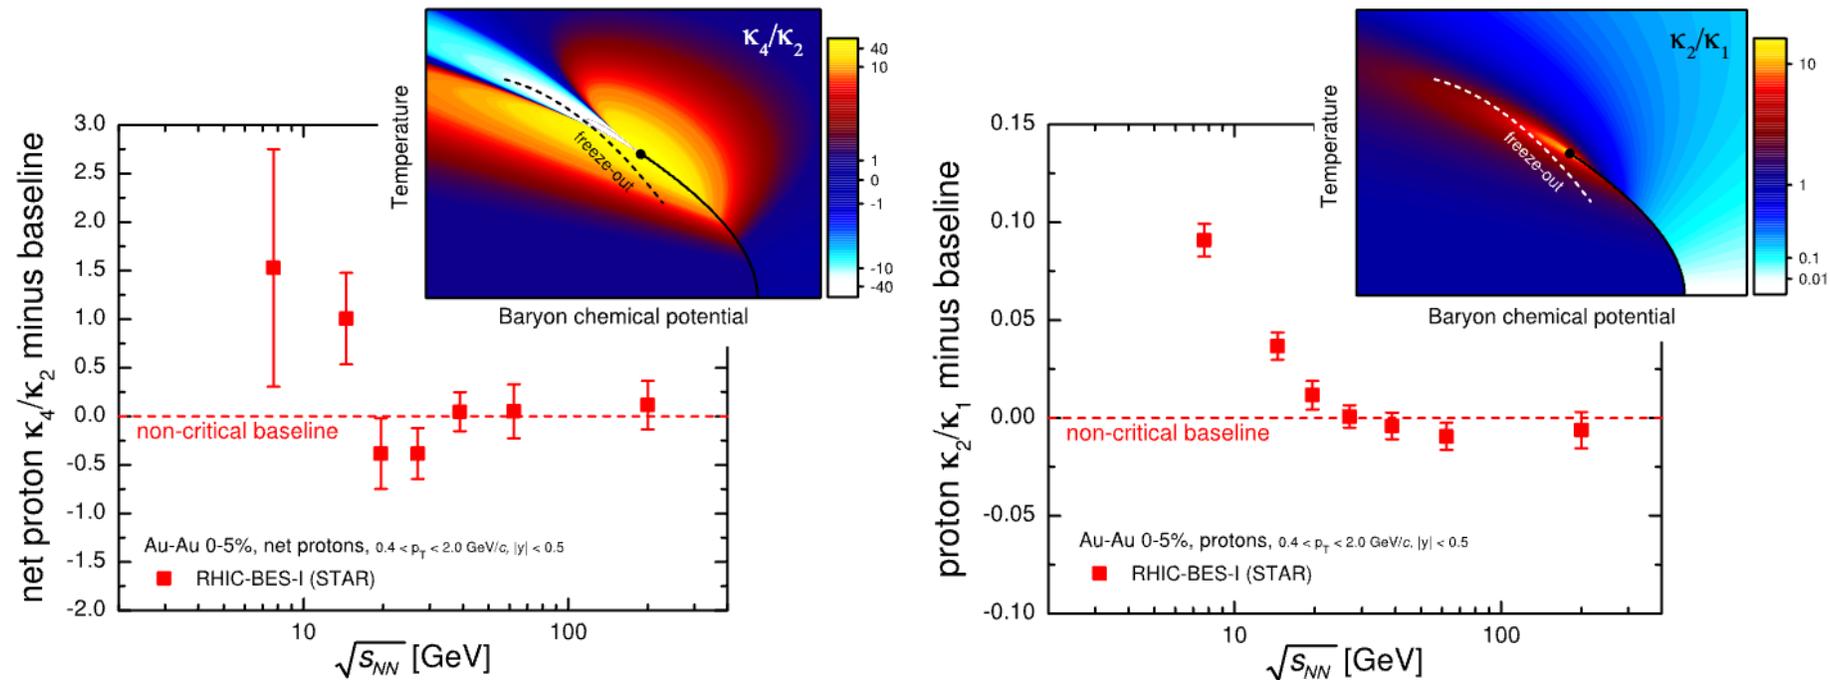

Fukushima, PRC (2014)

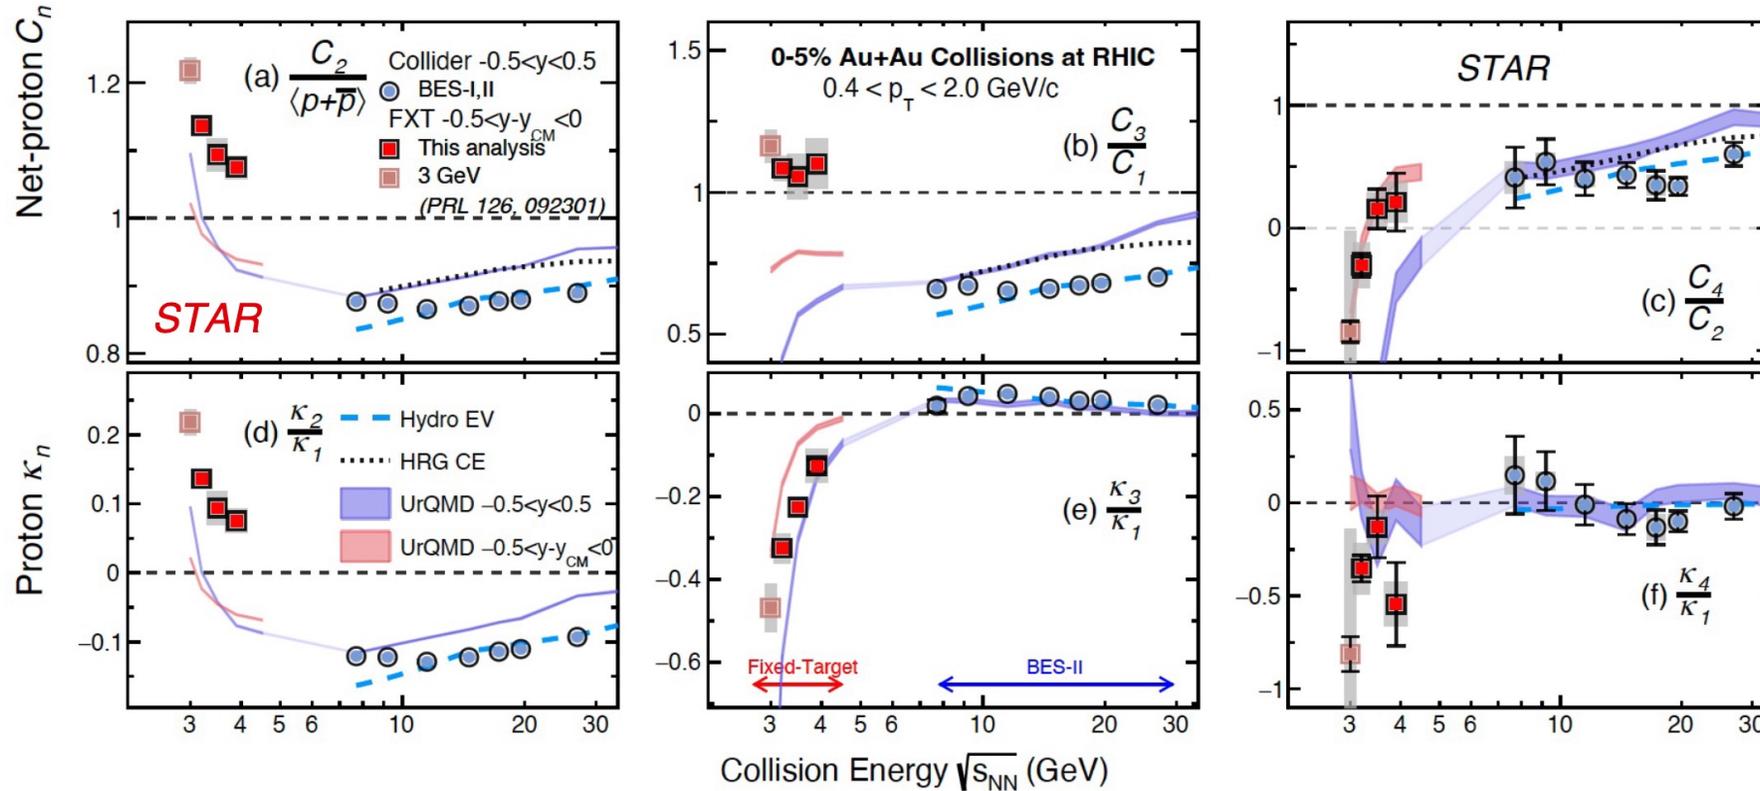

Sorensen, Koch, PRC (2020)

Increasingly relevant at lower energies probed through RHIC-FXT

Subtracting the hydrodynamic non-critical baseline

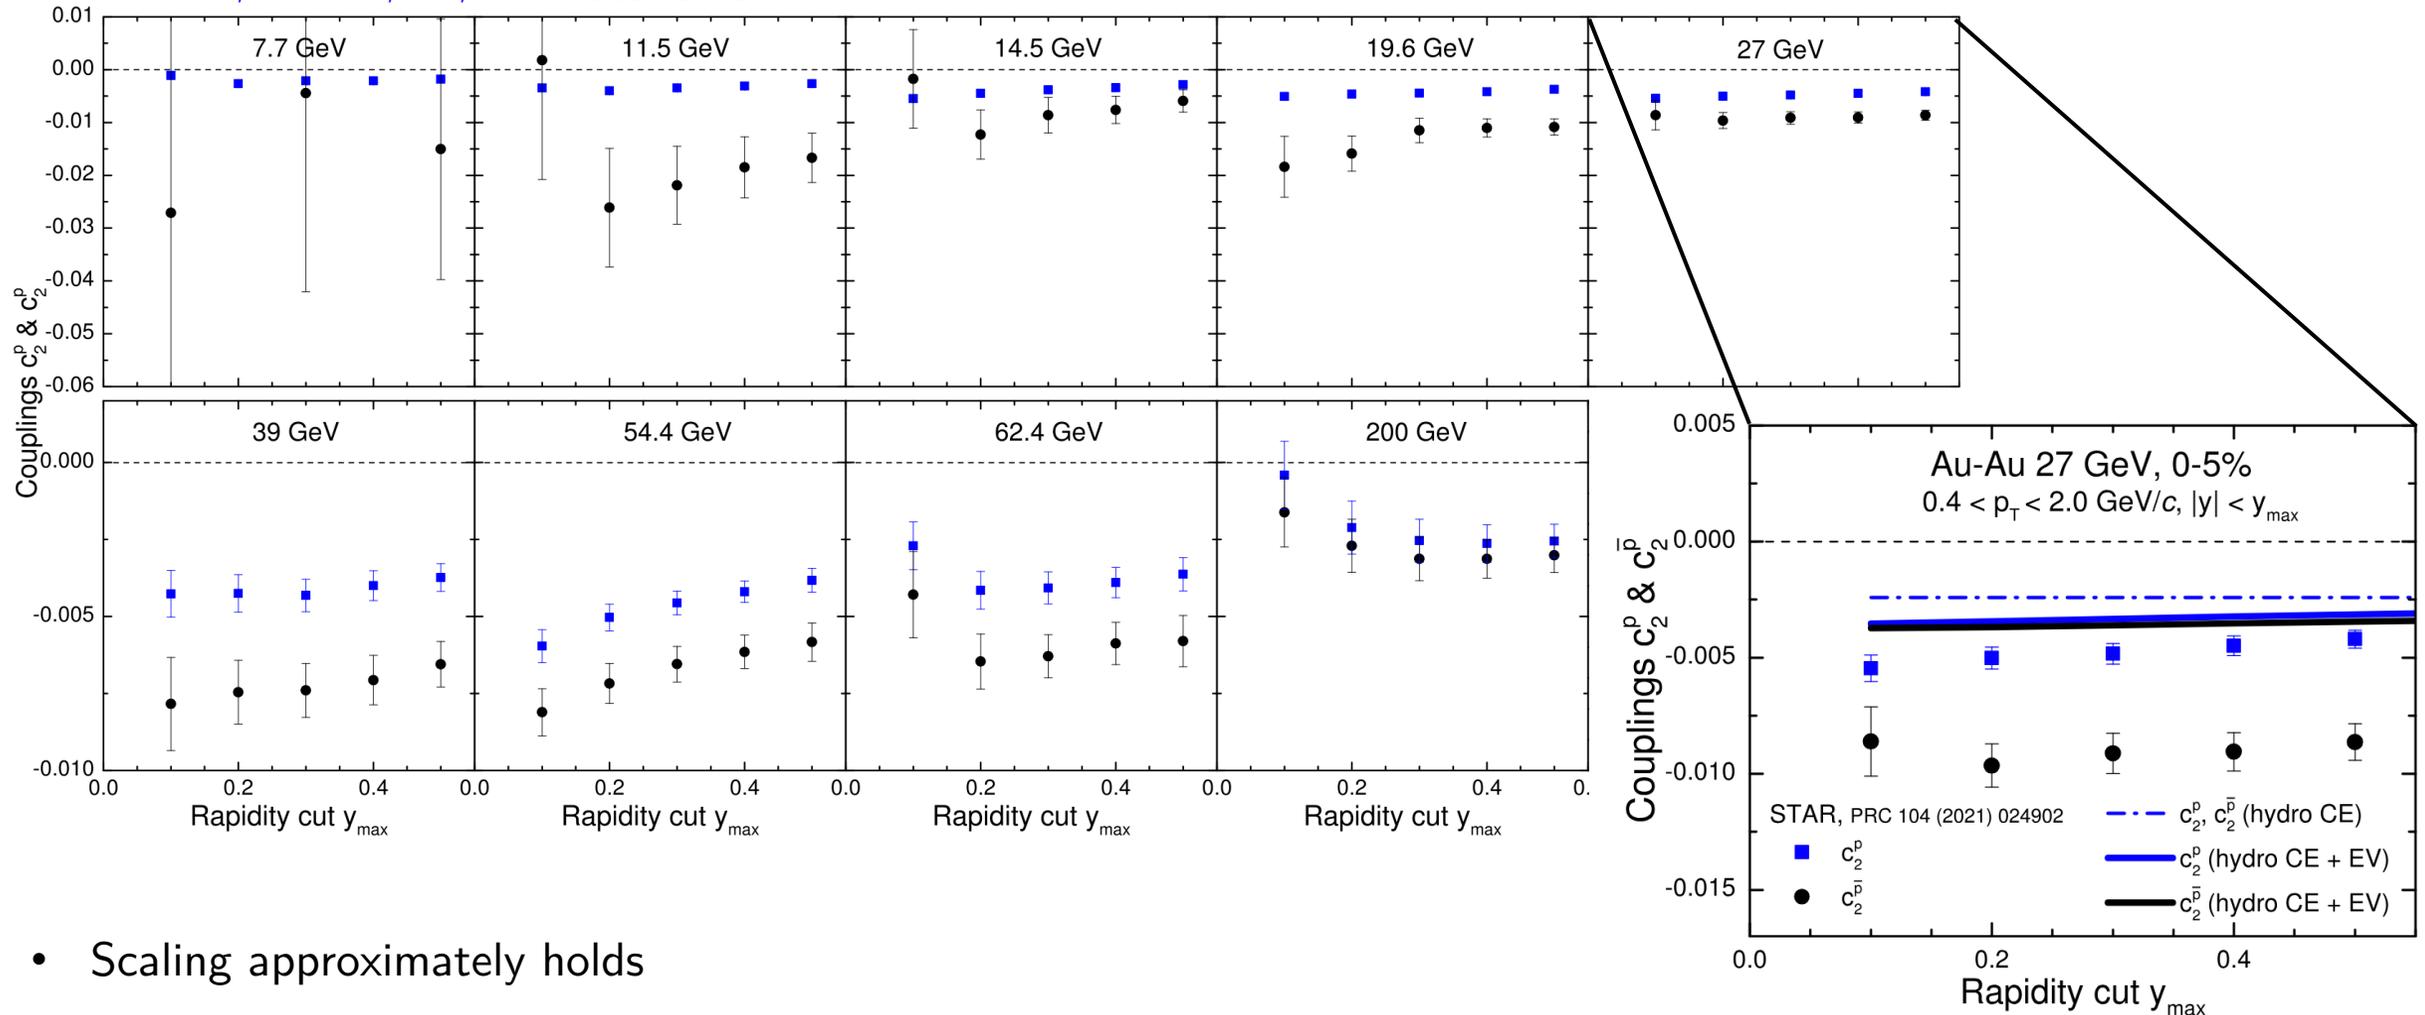

Z. Sweger (STAR), QM2025

- Continues the trends seen at lowest collider energies, in a fairly dramatic fashion
- **UrQMD (cascade) describes reasonably well the qualitative features**
 - Dominance of non-critical effects (centrality selection and spectators)?

Scaled factorial cumulants from RHIC-BES-I

A. Bzdak, V. Koch, VV, arXiv:2503.16405

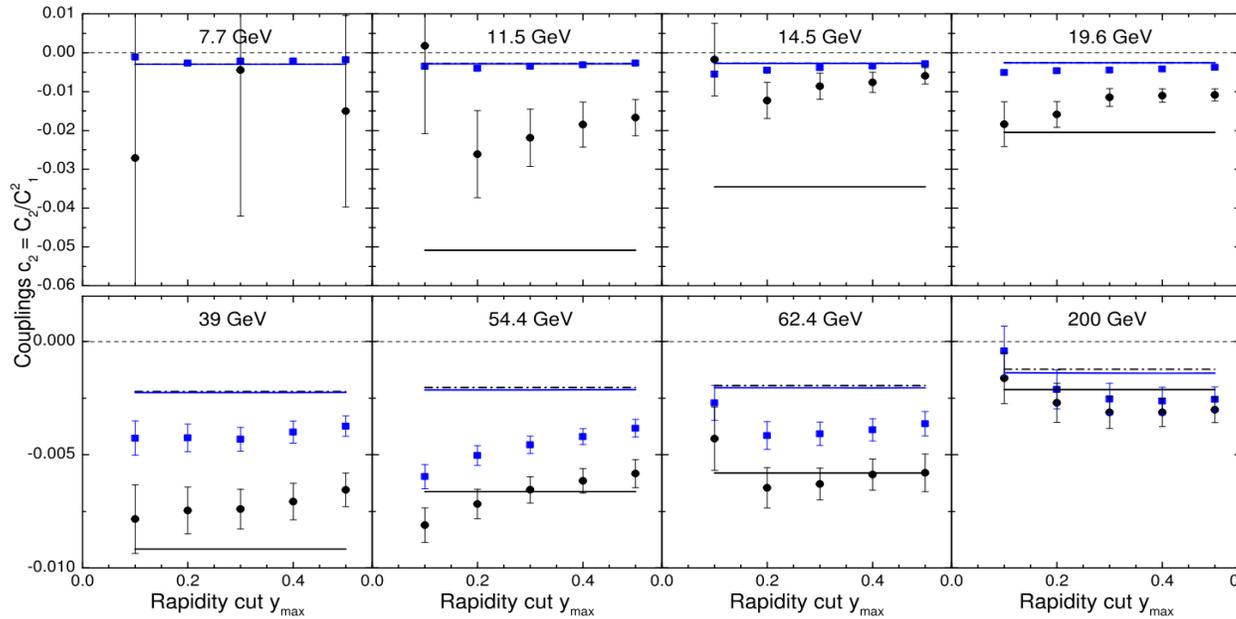

- Scaling approximately holds
- But significant difference between p and \bar{p} in BES-I and hydro fails – **the antiproton puzzle**
no single thermalized fireball?

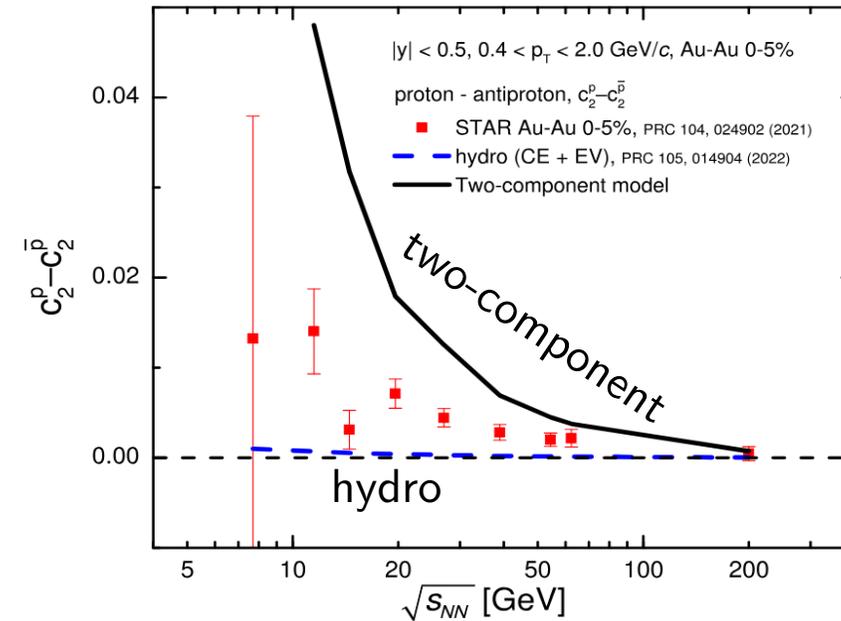

The antiproton puzzle and the two-component model

Two-component model: produced ($p\bar{p}$ pairs) and stopped protons comprise from two independent sources

The data lie in-between single and two-fireball models

Difference between p and \bar{p}

A. Bzdak, V. Koch, VV, arXiv:2503.16405

Opportunities for BES-II:

- Further tests of the splitting between p and \bar{p} in 2nd order cumulants with extended y coverage
- Critical point signal expected to break the scaling

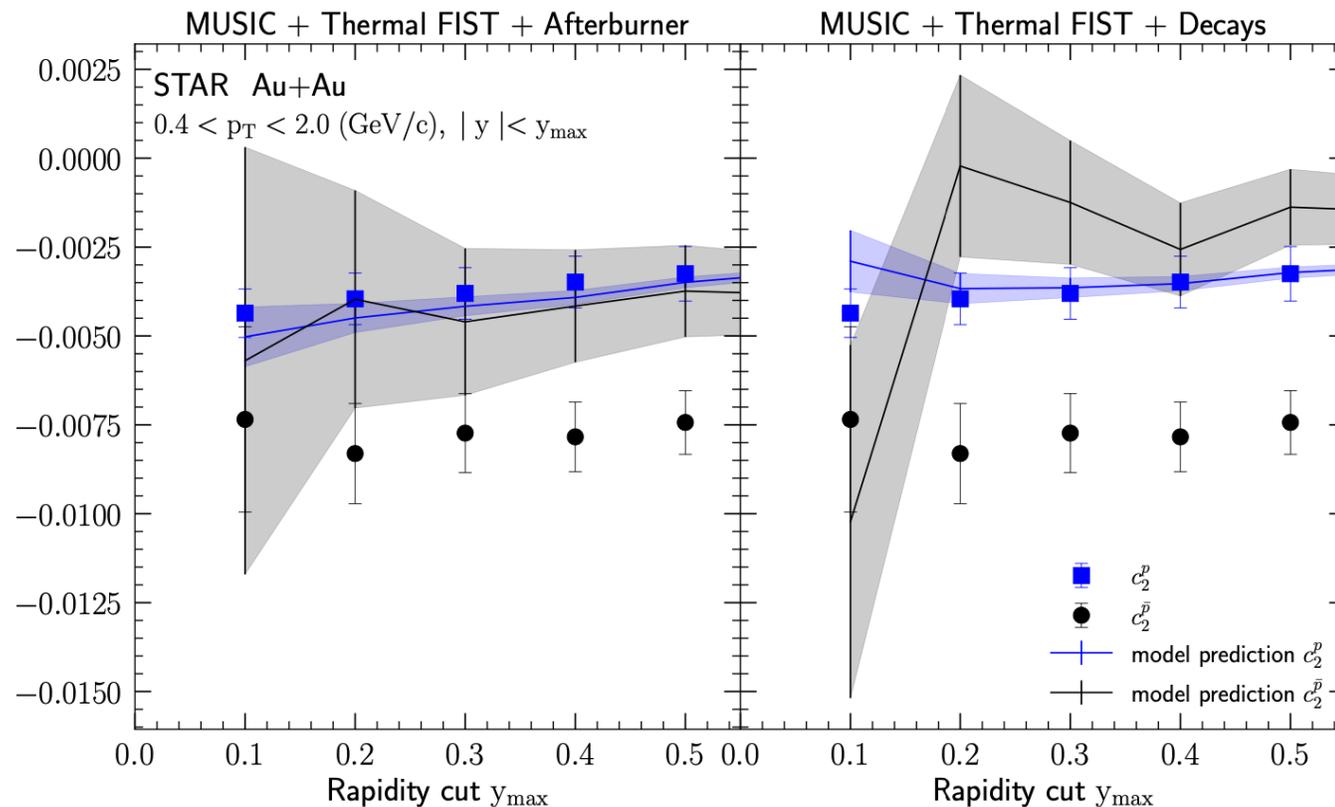

$$\frac{\hat{C}_n}{(\hat{C}_1)^n} = \text{const.}$$

[Ling, Stephanov, PRC 93, 034915 (2016)]

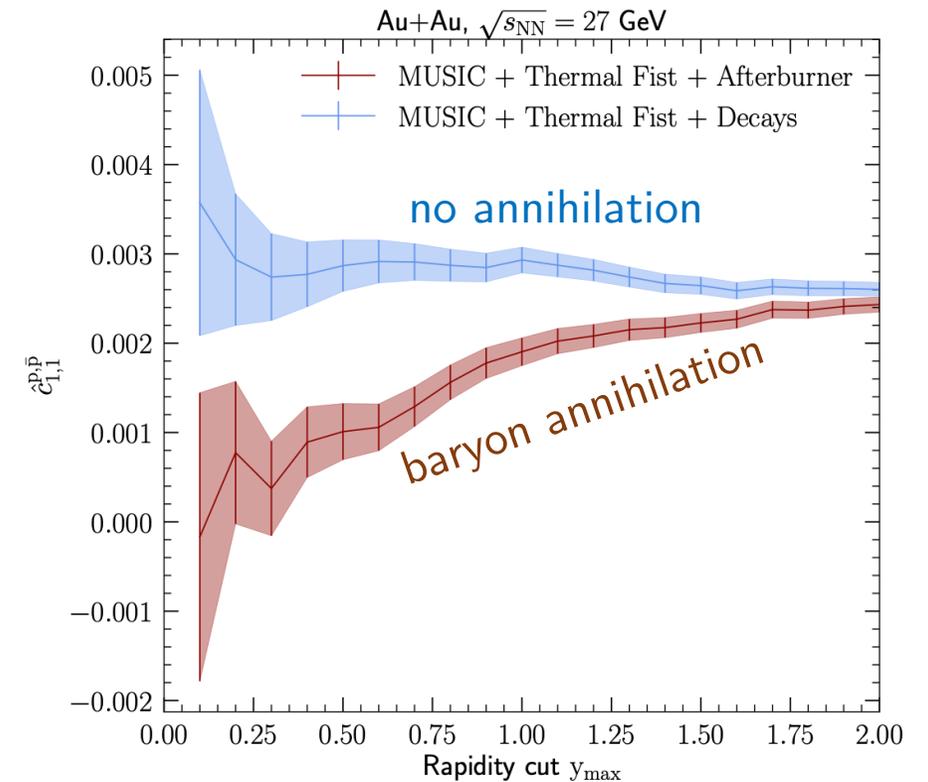

Scaled factorial cumulants and baryon annihilation

Extending Hydro EV to incorporate hadronic phase (UrQMD)

Au-Au, $\sqrt{s_{NN}} = 27$ GeV G. Pihan, VV, in preparation

Covariance $c_{11}^{p\bar{p}}$

- Hadronic phase appears unlikely to resolve the antiproton puzzle (more statistics needed)
- Acceptance dependence of proton-antiproton covariance shows clear signature of hadronic phase

Non-critical cumulants
